Radiation Survey of Proposed Birch Island Project of  
Consolidated Rexspar Minerals and Chemicals Limited  
Birch Island, British Columbia

In company with Mr. Ron Ripley and Bert Haywood, residents in the Birch Island area, a radiation survey was made about the proposed Birch Island Project of Consolidated Rexspar Minerals and Chemicals Limited on May 30, 1978. The equipment used was as follows:-

Air samples were taken with a H & H Custom Work diaphragm air pump with pulsation damper. The pump was calibrated at a flow rate of 8.8 liters per minute using a wet test meter. A Sartorius membrane filter, 25 mm in diameter with a 0.8 micron pore size was used to collect the sample. A Tri-Met Instruments Ltd., Model TM372A alpha counter equipped with a foil type open zinc sulphide detector was used to evaluate the radiation. A certified AM-241 alpha standard was used to calibrate the instrument before and after the sampling project. The Atomic Energy Control Regulations, Registration SOR/78-58, 16 January, 1978, Schedule 11, Maximum Permissible Doses and Exposures, Table Column II. Any Other Person, limit the radiation exposure in the home or in other non-occupational situations as follows: "the maximum permissible annual average concentration of radon daughters attributable to the operation of a nuclear facility shall be 0.02 W.L. (work level)." There were no concentrations found above this limit in the ambient air about the proposed site.

Following are the results of the survey:-

RADIATION SURVEY OF PROPOSED BIRCH ISLAND PROJECT

MAY 30, 1978

Sample No.	Time of Sample	Time of Reading (Δt)	Sampling Time (Min)	Counting Time (Min)	Number of Counts	Average Count	Location	W.L.

## Underground

The adit entrance to the underground workings at the three adit locations had at one time been closed off to prevent inadvertent access by unauthorized persons. The fencing had been partially removed by persons unknown so that entry is possible by any person. This condition must be immediately corrected to prevent access to any of the underground workings by unauthorized persons.

The BD zone underground workings are all dead ends. This means that the only ventilation possible would be by convection due to temperature variance between the mine workings air and the ambient outside atmosphere. This means of air movement decreases in direct ratio with the length of the underground workings and temperature variance between the underground and ambient atmosphere temperature. There would only be minimal air movement from the underground workings proper to the outside atmosphere. The immediate portal area would be flushed by surface breezes. The high underground radon daughter concentrations can be attributed to the minimal air circulation and the long period of underground working dormancy. The radon gas and daughters that reach the outside atmosphere are very quickly diluted by natural air currents to levels well below the established permissible limits.

Following are the results obtained in the BD zone underground workings together with a sketch showing the location of the samples:-

UNDERGROUND SAMPLES

## NOTES TO SCHEDULE II

- (1) The maximum permissible doses and exposures specified in this Table do not apply to ionizing radiation
- (a) received by a patient in the course of medical diagnosis or treatment by a qualified medical practitioner; or
- (b) received by a person carrying out emergency procedures undertaken to avert danger to human life.
- (2) The Board may, under extraordinary circumstances, permit single or accumulated doses or exposures up to twice the annual maximum permissible doses or exposures for atomic radiation workers. Such variance will not be granted
- (a) if appropriate alternatives are available;
- (b) for irradiation of the whole body or abdomen of women of reproductive capacity; or
- (c) for irradiation of the whole body, gonads or bone marrow if the average dose received from age 18 years up to and including the current year exceeds 5 rems per year.
- (3) In determining the dose, the contribution from sources of ionizing radiation both inside and outside the body shall be included.
- (4) The dose to the abdomen shall not exceed 0.2 rem per two weeks, and if the person is known to be pregnant, the dose to the abdomen shall not exceed 1 rem during the remaining period of pregnancy.
- (5) The dose to the thyroid of a person under the age of 16 years shall not exceed 1.5 rems per year.
- (6) For exposures to radon daughters, the maximum permissible exposures (in working level months) apply instead of the maximum permissible doses for the lungs (in rems).
- (7) The WLM unit is not appropriate for exposures in the home or in other non-occupational situations. In such situations, the maximum permissible annual average concentration of radon daughters attributable to the operation of a nuclear facility shall be 0.02 WL."

## NOTES À L'ANNEXE II

- (1) Les doses et les expositions maximales admissibles indiquées dans ce tableau ne s'appliquent pas aux rayonnements ionisants
- a) reçus par un patient lors d'un examen médical ou de soins donnés par un médecin compétent ou
- b) reçus par une personne exécutant des mesures d'urgence pour prévenir un danger pour la vie humaine.
- (2) La Commission peut, en des circonstances exceptionnelles, permettre qu'une dose ou une exposition atteigne le double du taux admissible par année pour les travailleurs sous rayonnements. Cette dérogation n'est pas accordée
- a) s'il existe d'autres solutions,
- b) pour l'irradiation de tout le corps ou de l'abdomen de femmes fécondes ou
- c) pour l'irradiation de tout le corps, des gonades ou de la moëlle des os, si la dose moyenne reçue depuis l'âge de 18 ans, jusqu'à et compris l'année en cours, dépasse 5 rems par année.
- (3) En déterminant cette dose, il faut tenir compte de l'apport des sources de rayonnements ionisants tant à l'intérieur qu'à l'extérieur du corps.
- (4) La dose reçue au niveau de l'abdomen ne peut dépasser 0,2 rem par période de deux semaines, toutefois, pour les femmes enceintes, cette dose ne peut dépasser 1 rem du moment de la connaissance de leur état jusqu'au terme de leur grossesse.
- (5) La dose reçue au niveau de la thyroïde d'une personne âgée de moins de 16 ans ne peut dépasser 1,5 rem par année.
- (6) Le taux d'exposition des poumons aux produits de filiation du radon est calculé selon l'exposition maximale admissible (calculée en WLM) plutôt que selon les doses maximales admissibles (calculées en rems).
- (7) Le tableau 2 ne s'applique pas aux expositions au foyer ou à l'extérieur du lieu du travail. Afin de limiter l'exposition qui pourrait exister, il faut se baser sur la concentration moyenne annuelle maximale de produits de filiation du radon attribuable à un établissement nucléaire. Cette concentration est alors d'au plus 0,02 WL.

SUMMARY

82M/12W  
82M-21

During 1969, exploration and development work was carried out by Denison Mines Limited at the Rexspar property at Birch Island, B. C. The programme started in late April and continued throughout the year.

Surface exploration, including line cutting, geochemical soil sampling, induced polarization scintillometer and radon surveys and geological mapping was carried out. In August a programme of diamond drilling, using two machines got under way and was in progress at the year end. To date 24 holes for a total of 7035 feet were drilled on the exploration programme and five holes for another 675 feet were drilled in the fluorite zone.

Three new areas in the north east part of the property have been found to be underlain by the favourable uranium bearing pyrite mica formation. Intersections, which were below ore grade, assayed from .2 to 1.17 lbs. / ton across widths of 6 to 58 feet. The "F" zone is also considered a very favourable area though drill core recovery and results were disappointing.

A geochemical soil survey outlined a large and significant molybdenum anomaly. This anomaly occurs along the ridge of a hill. It covers the fluorite zone, but is mostly above and to the south of it. The location of the anomaly would indicate that the source is other than from the fluorite zone.

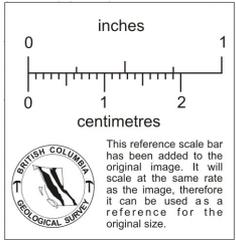

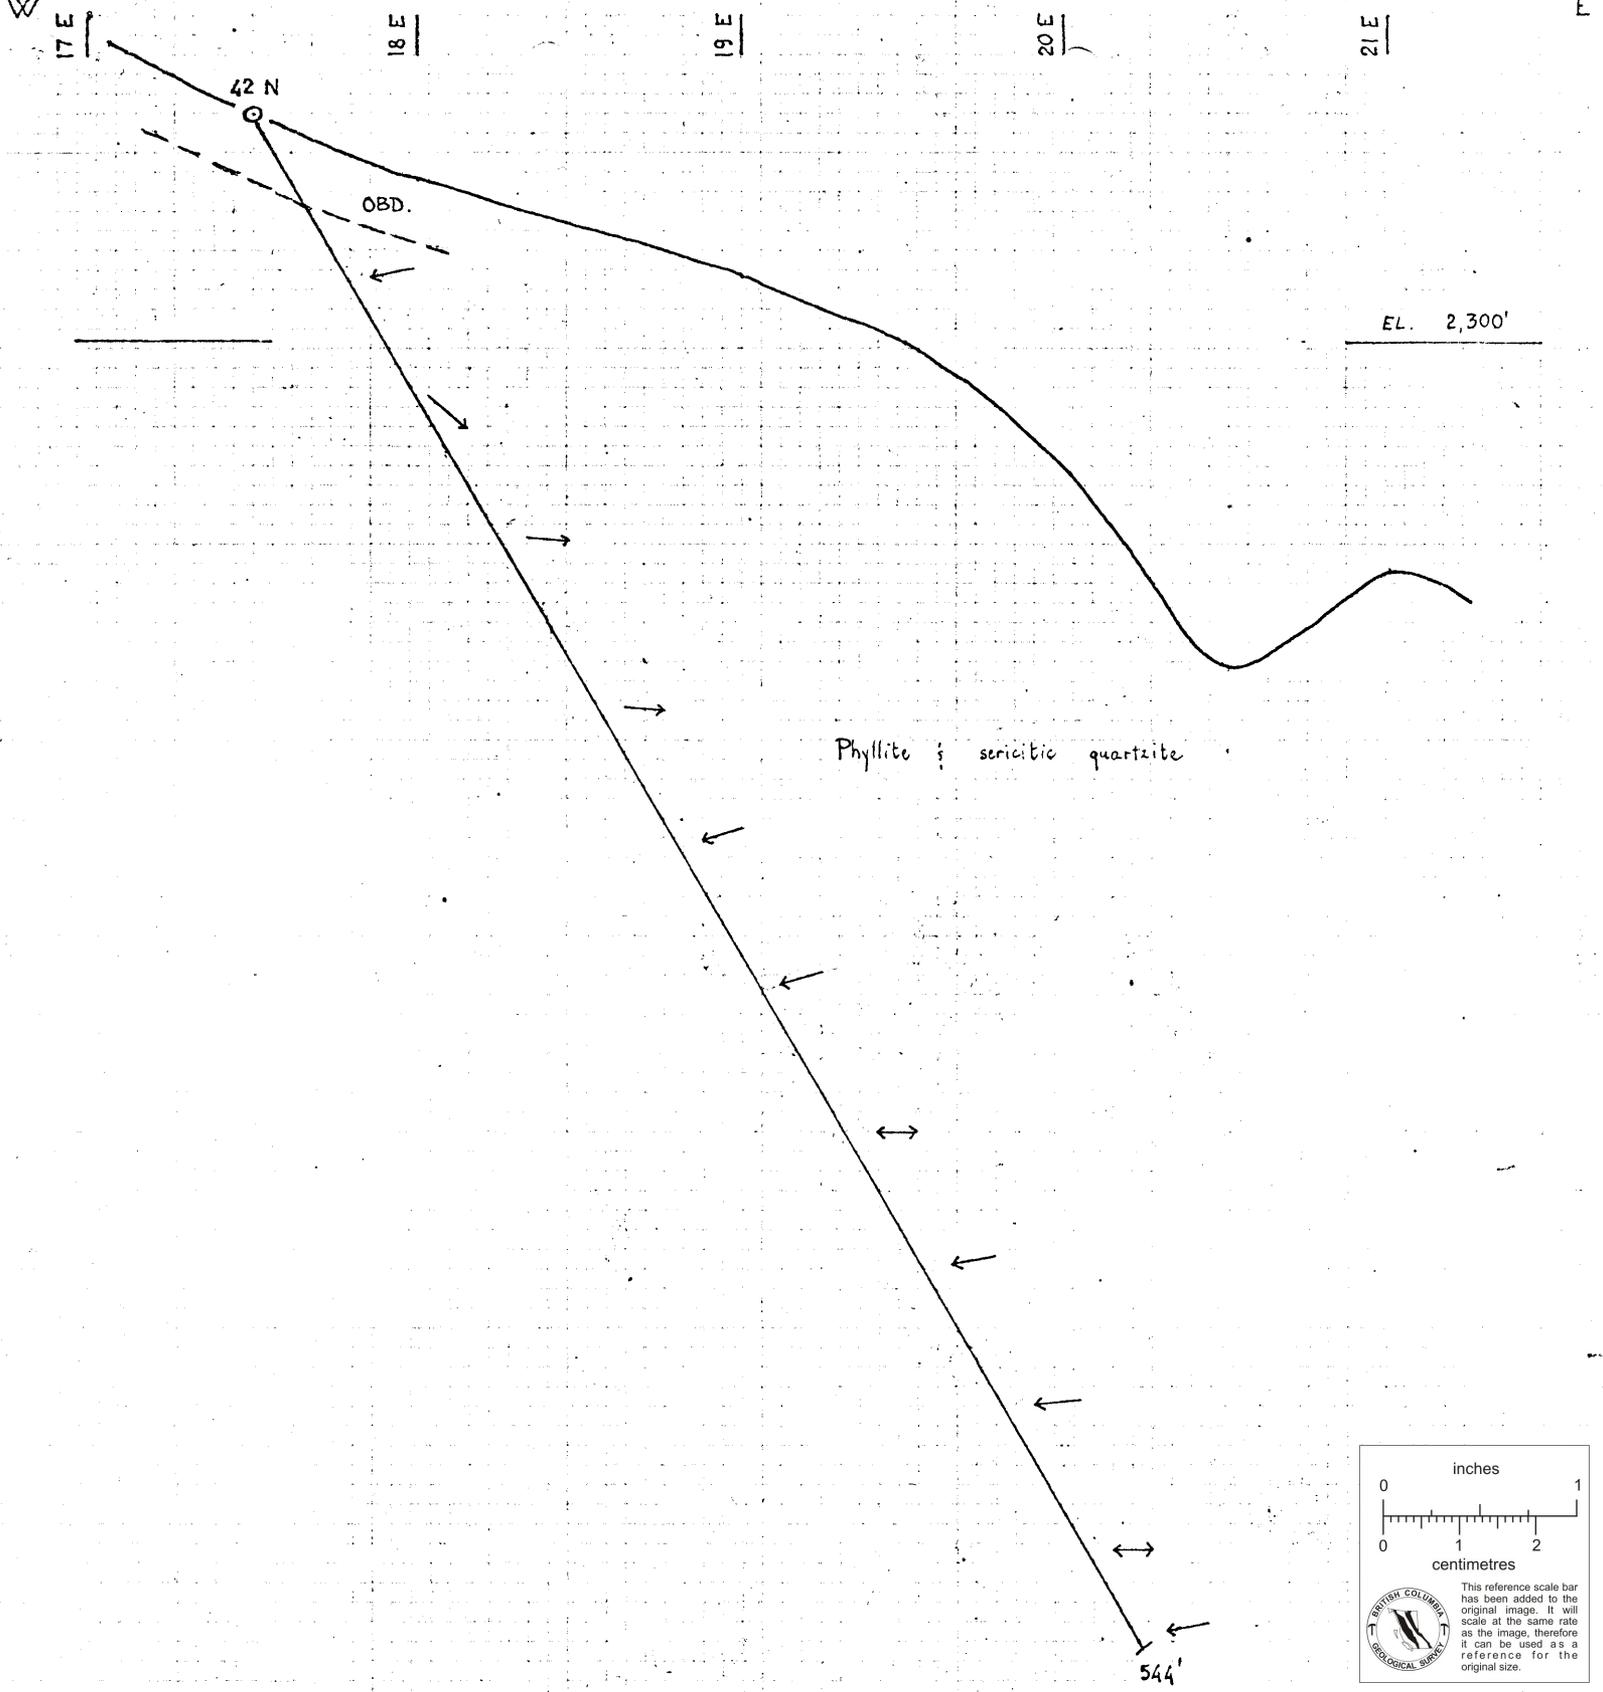

From recent drilling carried out on the fluorite zone, significant amounts of molybdenite and strontium have been indicated. The grade of the fluorite has been confirmed and the extent of the zone along strike has been increased.

A programme of grid drilling is required to fully evaluate the uranium bearing areas. Additional drill will be required as well to check other untested zones. A programme of tractor trenching is planned to investigate the areas of the molybdenum anomaly. On the fluorspar zone, a programme of bulk sampling is being initiated. This work will be followed by appropriate metallurgical test work. If satisfactory results are obtained from the bulk sampling and metallurgical test work a feasibility study will be undertaken.

At this stage too many information gaps exist in favourable areas within the property to ignore the possible existence of other uranium or fluorite ore zones or an economic deposit of molybdenite mineralization. It is felt that additional exploration work is well warranted.
