PROFILE

T.K.

SUMMARY GEOLOGY (lithology, age, structure, alteration, mineralization, size, and attitude):

Rhyolites of andesites flows, breccias, and tuff of
probable Cretaceous age are intruded by Cretaceous
Granites. Mineralization is galena, sphalerite and pyrite
associated with breccias.

TSALIT MOUNTAIN

PROSPECTING REPORT (93L/2)

INTRODUCTION:

Work has been done on the Tsalit Property by a number of operators since 1929, when copper-moly mineralization was just discovered. Descriptions are given under the name of "Grubstake Group" in relevant Annual Reports to the Minister of Mines in British Columbia and Geological Survey of Canada Publications.

Key claims in the showings area were held by E. Westgarde, of Houston, BC, during the mid-60's. A deep drill hole was completed by New Nadina Explorations in the 70's. This hole was collared in mineralization. Unfortunately, the hole was cased through Cu-Ag mineralization at surface, and thereafter drilled through a series of barren andesitic pyroclasts.

The 1988 work done on these claims was for the present owners, New Nadina Exploration Ltd. This work consisted of, in part, prospecting by Mr. Pat Suratt. These traverses and subsequent sampling form the basis for this report.

LOCATION AND ACCESS:

Tsalit Mountain is located about 25 km southwest of Houston, BC. The property is on the north side of the upper part of Tsalit Mountain. It is accessible with difficulty using all terrane vehicles on unmaintained trails from logging slashes, north of Puport Creek. Some use was made of road based access, but in order to facilitate effective usage of time, a helicopter, based from Houston was used for mobilization and demobilization of a fly-camp.

The property is centered at 54° 09' north latitude and 126° 52' west longitude.

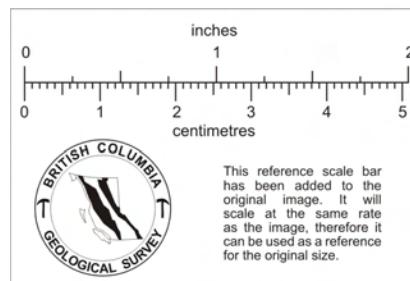

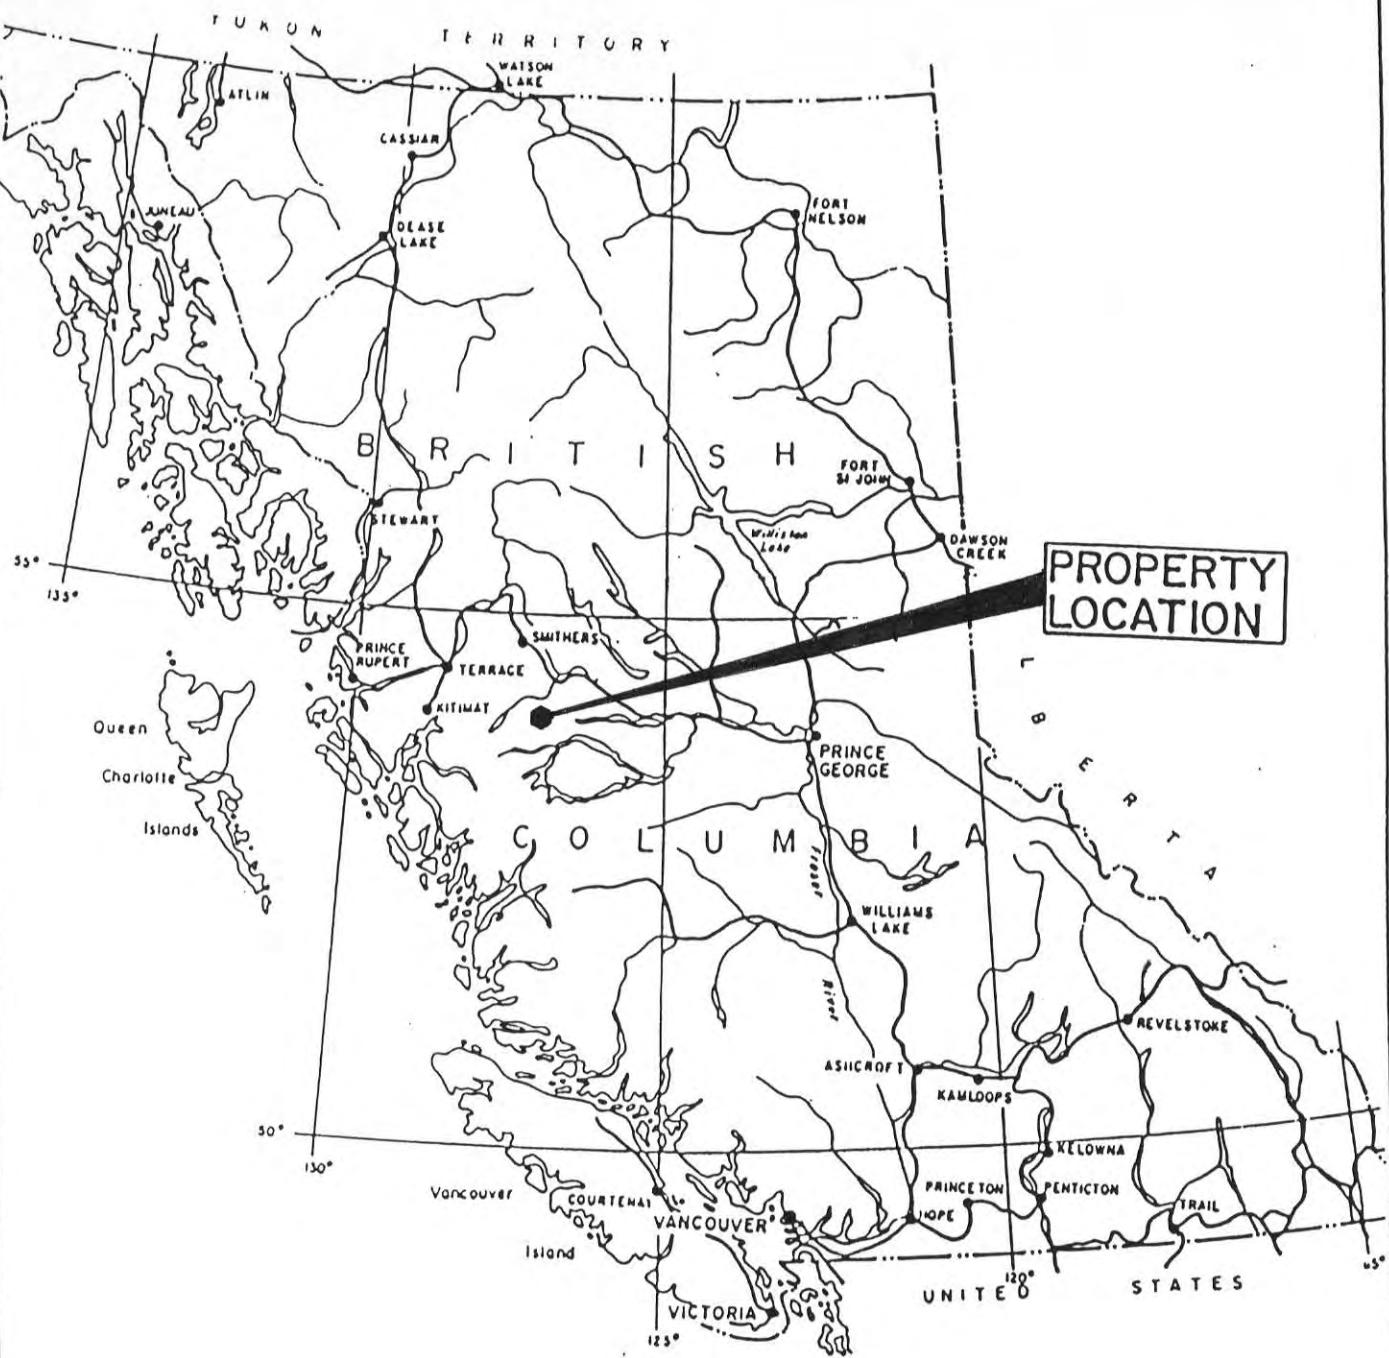

CLAIMS AND OWNERSHIP:

The property comprises one claim, Tsalit 1, of 12 units, record no. 811, expiry date is on September 30, 1991.

The claim was staked by Mr. Ronald R. Blusson, and sold by Bill of Sale # 4995, to New Nadina Exploration Ltd, on February 16, 1983.

REGIONAL GEOLOGIC SETTING:

The region is situated along the west-central part of the Stikine Terrane. Stratified and plutonic rocks range in age from Upper Paleozoic to Early Tertiary, with rocks of Jurassic age and younger being dominant (Figure 3, Table 1).

0 100 200 300 400 500 MILES
0 100 200 300 400 500 KM.

NEW NADINA EXPLORATION LOCATION MAP

TSALIT 1 Mineral Claim

Nov 21/88	DATE:
SCALE AS SHOWN	FIGURE NO. 1

Four major tectono-stratigraphic elements dominate the region.

The Lower and Middle Jurassic Hazelton Group comprises a marine and non-marine arc assemblage that is the preponderant rock assemblage in the area of interest. These strata are mainly non-marine rhyolitic to andesitic flows, pyroclastics and hypabyssal intrusives comprised of interfingering assemblages of flows, ignimbrites, lahars, air fall tuffs and breccias, volcaniclastic sediments and high level intrusive units. Consanguineous with the volcanics are diorite to granite plugs and stocks of the Topley Intrusions.

The interval between Upper Jurassic and Early Upper Cretaceous time is occupied by two sedimentary assemblages that appear to have little bearing on mineralization in this area.

To the immediate north of the area of interest, Upper Jurassic to mid-Lower Cretaceous Bowser Lake Group comprise a northwardly thickening wedge of deltaic-foredeep deposits. The source of the sediments was the Hazelton Group to the south and the depositional basin is known as the Bowser Basin. The locus of the strand lines across the southern limit of the Bowser Basin defines a structure known as the Skeena Arch, one of the most intensely mineralized belts in the Canadian Cordillera.

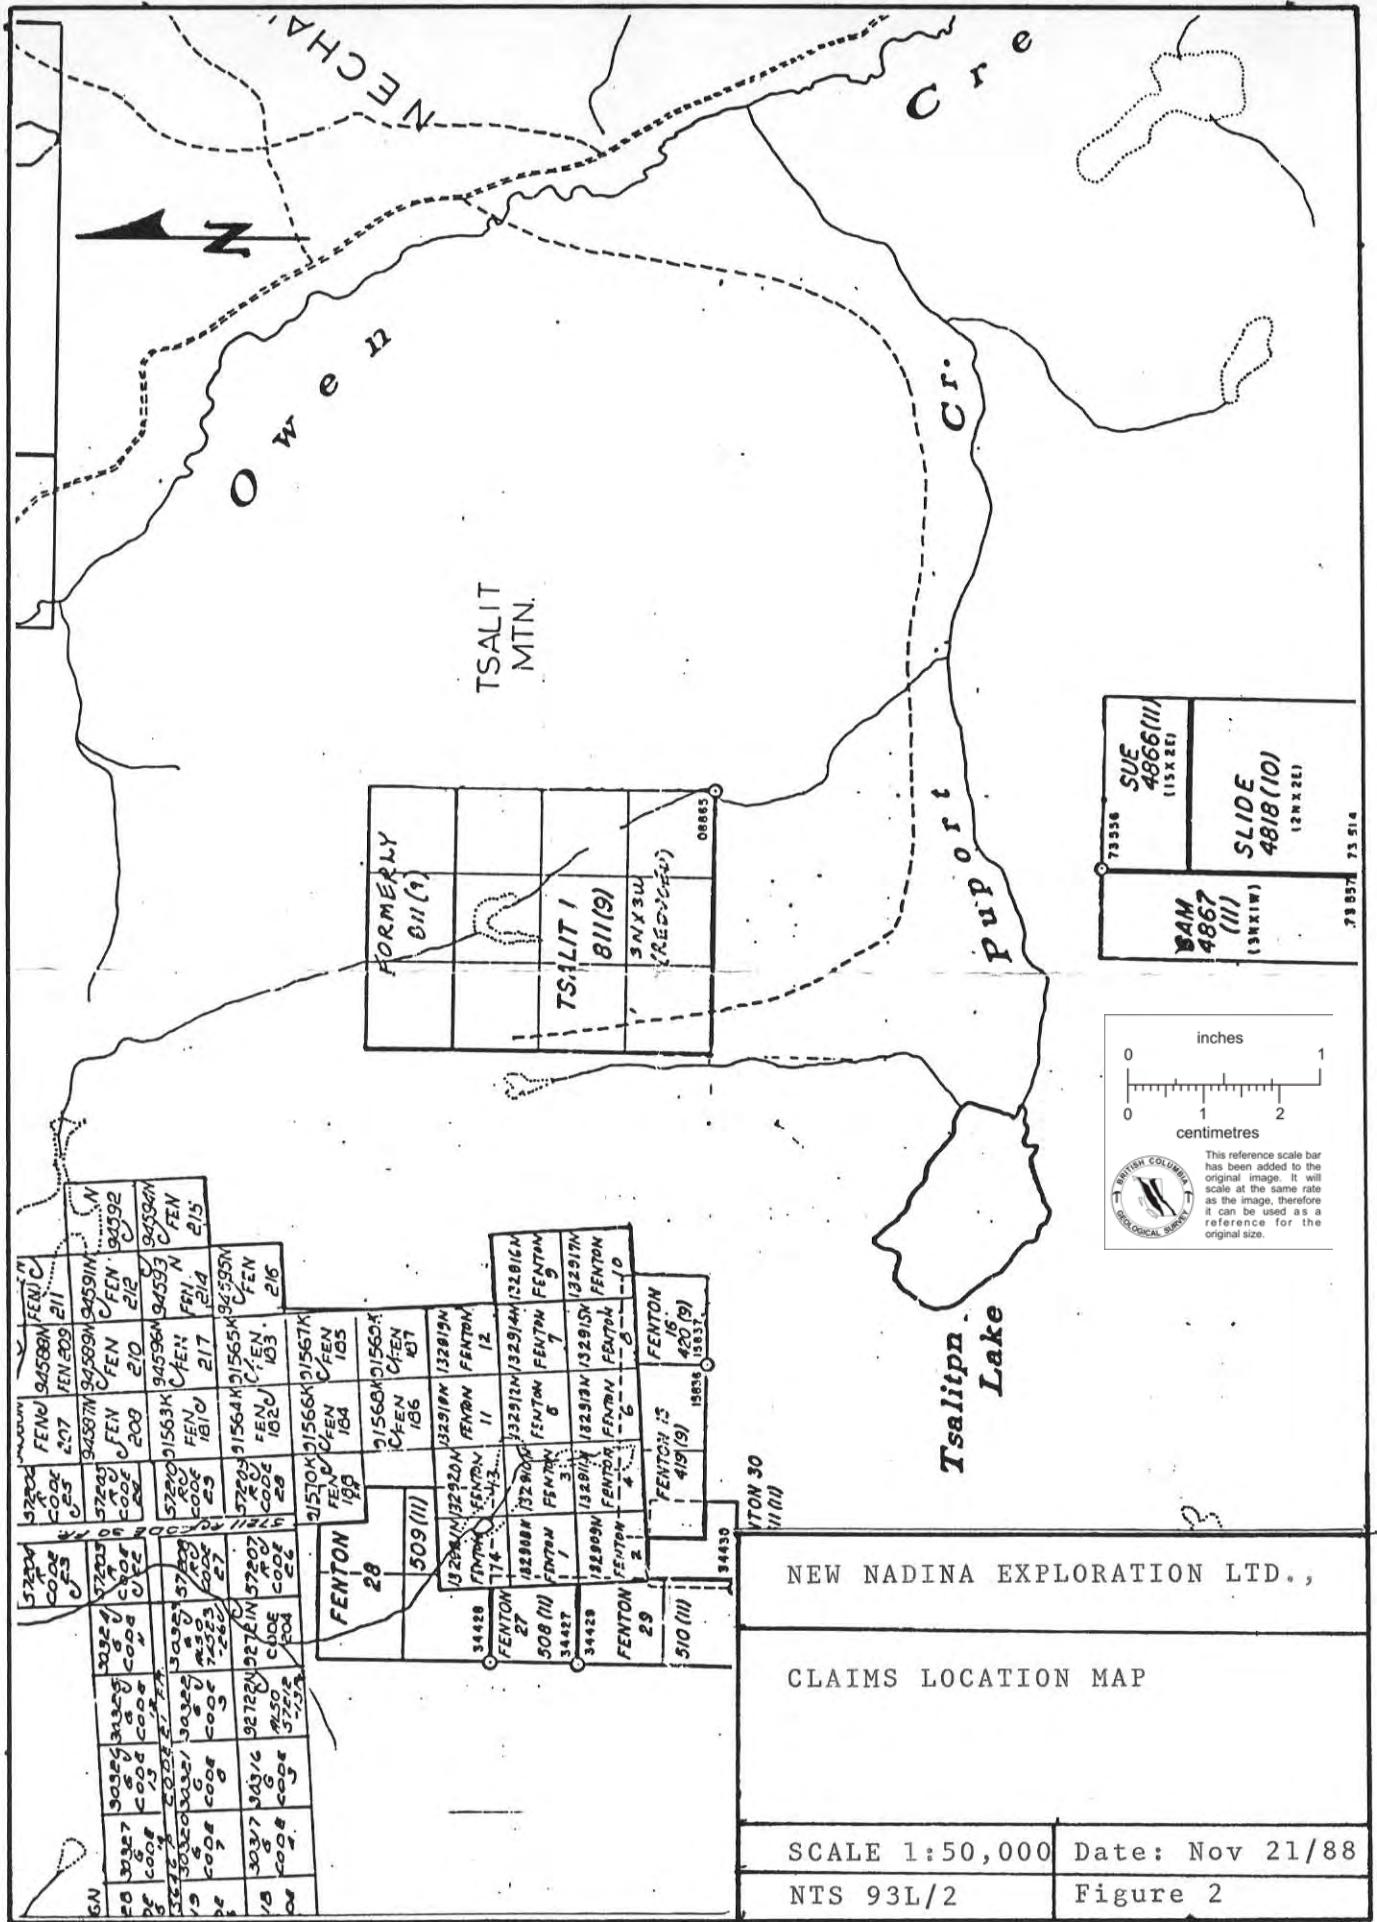

Between the mid-Lower Cretaceous and early Upper Cretaceous, the Skeena Group sediments were deposited across the entire region. This unit represents a continental margin clastic wedge, whose sediments were derived from the east, off the Omineca Terrane.

The late Upper Cretaceous to Eocene time is represented by a suite of continental transtensional arc volcanics that were deposited in an array of down-drop volcanic basins within the Stikine Terrane from latitude 55 30'N southward. These volcanics (the Kasalka and Ootsa Lake Groups) and their coeval intrusives (Bulkley, Babine, Nanika) are associated with the development of basin and range geomorphology that typifies this segment of the Stikine Terrane.

Post-Eocene time was one of uplift, erosion and local deposition of basalt. It served to expose mineralization.

Early and Middle Jurassic age arc-related mineralization is widespread and precious metals based. Included within this epoch is the Toodoggone gold silver camp, and the major deposits of Silbak-Premier, Big Missouri and Granduc along the east flank of the Coast Range. Mineralization in the Smithers-Whitesail area likely of this epoch includes the Dome Mountain deposits and those of the Topley-Richfield area.

Late Cretaceous - Early Tertiary aged mineralization in the Skeena Arch is presently the most varied, widespread and significant of the

two epochs. All the copper, molybdenum, tungsten and gold-bearing porphyries belong to this stage. Precious metals properties include Equity Silver, New Nadina, Silver Standard, Cronin and a host of smaller properties. Most of these deposits are related to the evolution of down-drop basins and calderas associated with volcanism, related plutonism and the development of a basin-and-range geomorphology. These deposits range from low temperature epithermal to high temperature mesothermal types.

PROPERTY GEOLOGY:

The area has been mapped and reported on by Church (1970 and 1972) and Tipper et al (1976), and the description of the geology is taken from these references.

The claims are underlain by andesite, basalt and minor rhyolite of probable Jurassic age, although rhyolite dykes and sills have been dated ($K/Ar: 76.5 \pm 3.0$ M.Y.) as Upper Cretaceous. Bed rock is restricted to prominent bluffs along the flanks of the hill, and isolated bed-rock knolls in the upper surface. Stratigraphic rocks include argillite overlain by rhyolite at lower elevations (Figure 4), overlain by basalt and andesitic lavas and tuff-breccias.

MINERALIZATION:

The main zone of mineralization on Tsalit Mountain is named the Grubstake Occurrence (Figure 5). The original showing was in a sheared and sericitized rhyolite with little azurite staining. A 10 foot sample across the zone gave 6.8oz/t Ag and 0.9% Cu (Ministry of Mines Rept., 1929, C175). Trenching showed this zone to consist of pyrrhotite, chalcopyrite, pyrite and sphalerite cementing, replacing and veining a tuff breccia composed of an andesitic matrix and rhyolitic breccia fragments.

Other showings on the mountain comprise the Summit Showing (Figure 5), comprising pyrite, pyrrhotite, molybdenite and chalcopyrite associated with a hornfelsed, amygduloidal basalt. Off the north slope of Tsalit Mountain, chalcopyrite, molybdenite and pyrite are found scattered in granitic rocks.

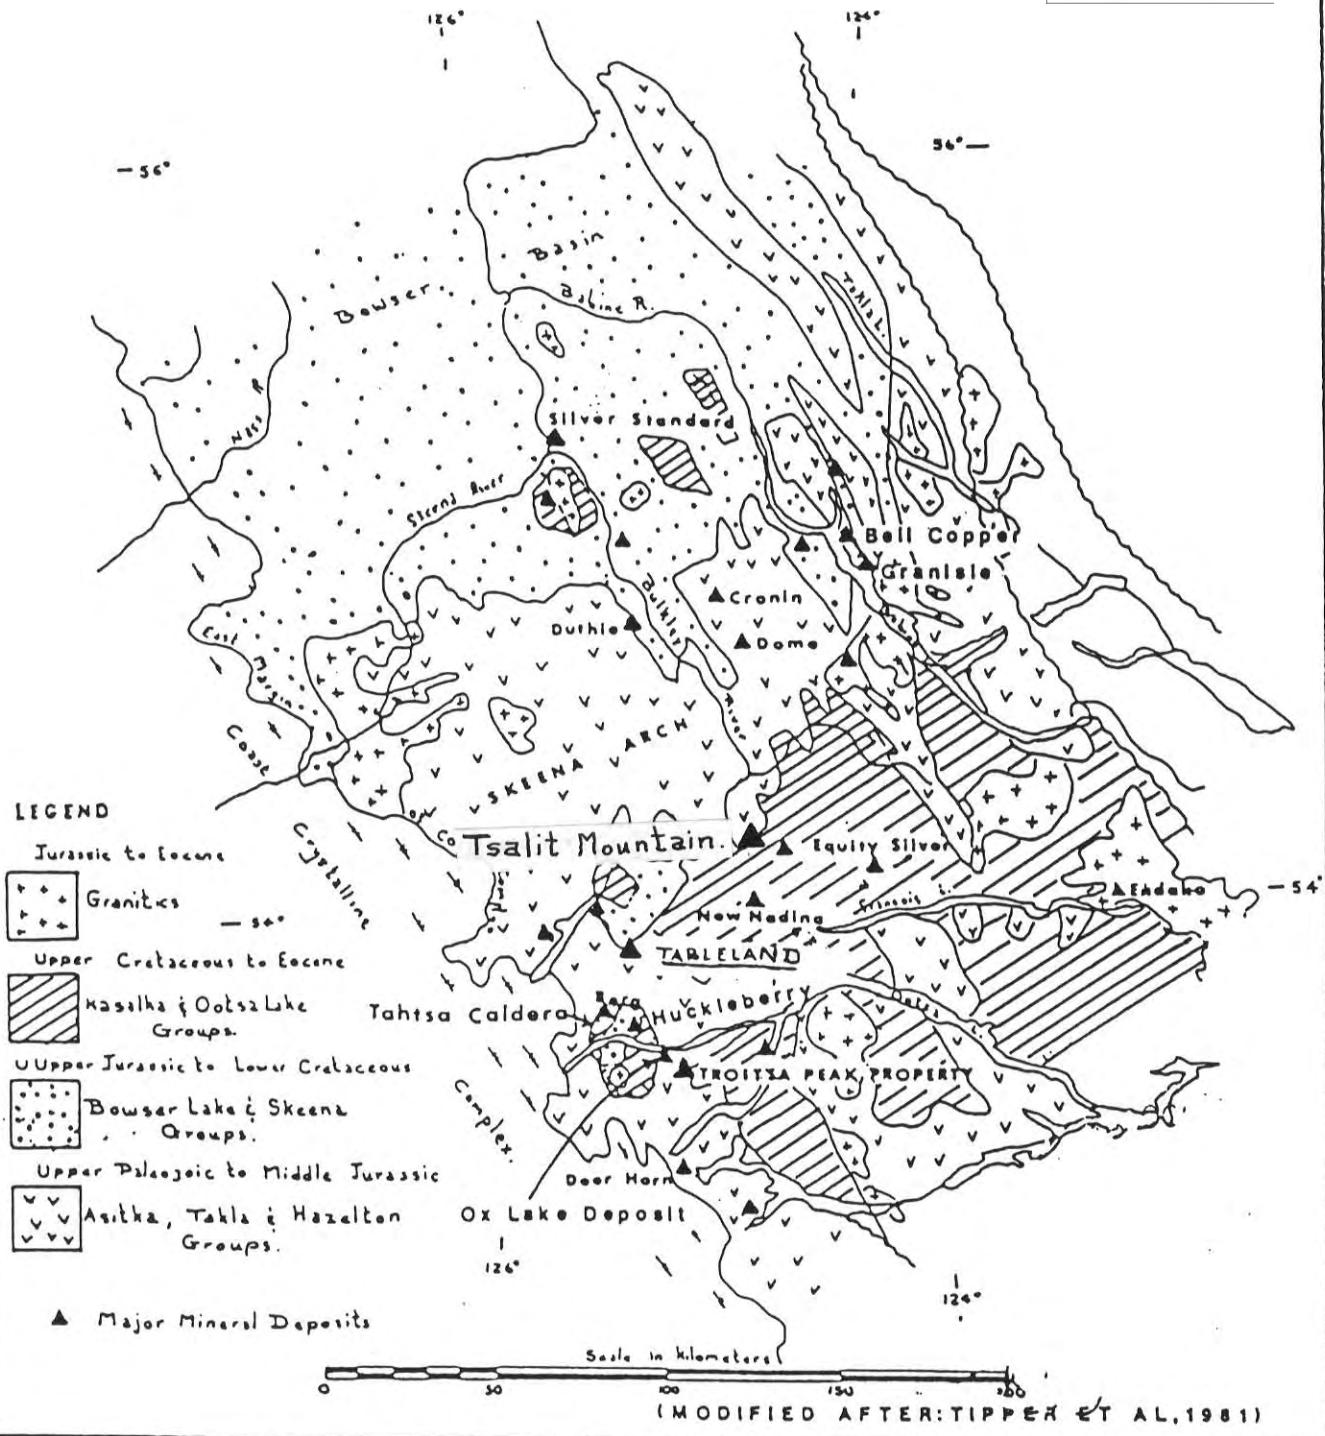

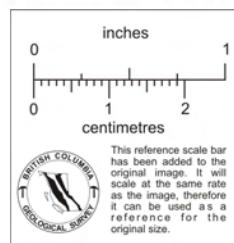

PROSPECTING 1988:

In order to assess the area for the presence of further showings, Mr. Pat Suratt in August, 1988 completed four prospecting traverses across the Tsalit Mountain area, on and adjacent the claims (Figure 6). Eight rock samples and four silt samples were collected.

None of these samples are from areas of mineralization with any known areal extent. Further prospecting is not likely to be effective in finding further mineralization. Dashed lines (Figure 6) roughly outline the traverses, and although well covered, things could be missed. The showings were not sampled, as they have been

Figure 3A

GEOLOGIC SETTING, MINERAL DEPOSITS
West-central British Columbia

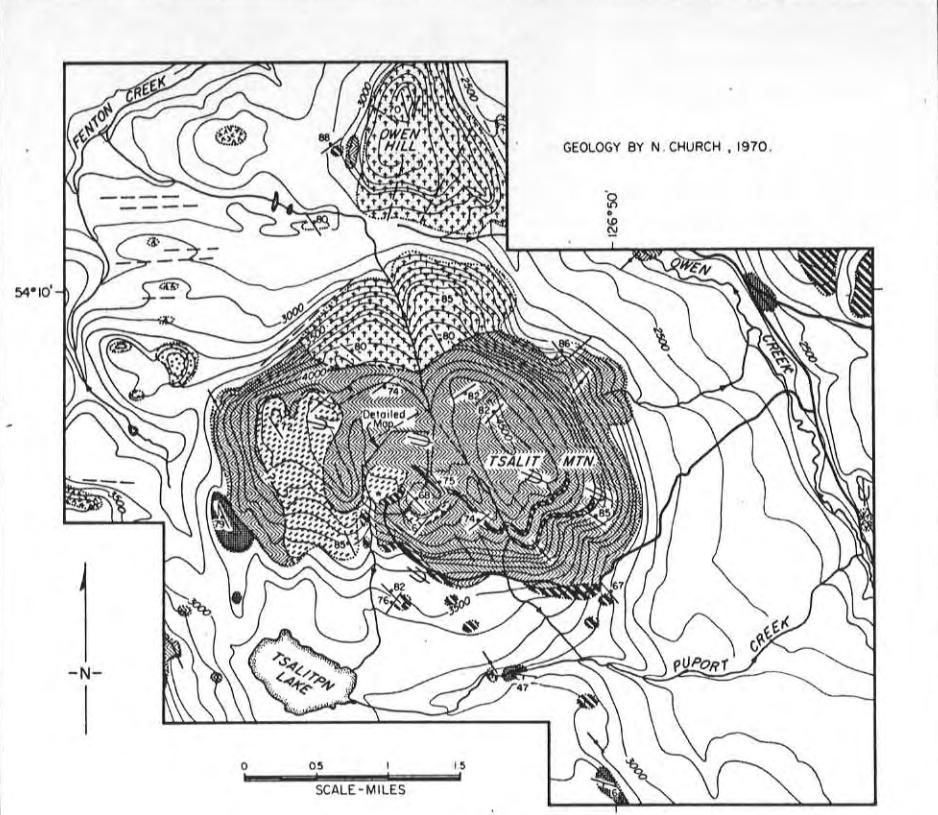

previously covered.

Soil samples in the area of rock sample PS504 and 505, and northward, should show whether mineralization is confined to the southpart of the mountain. Silt-3 (2.1 ppm Ag, 897 ppm Zn and 12 ppb Au) further points to the area of potential immediately north of PS505R.

AUTHOR'S STATEMENT:

I, Thomas A. Richards, of Box 436, Hazelton, BC, am the author of the report, "Tsalit 1 Claim, Prospecting - geochemical Report."

1. I received my B.Sc. from the University of British Columbia in 1965.
2. I received my PhD. from the University of British Columbia in 1971.
3. I am a Fellow of the Geological Association of Canada.
4. I have been involved in field research, and mineral exploration in British Columbia since 1963.
