## TRE GUIS MINERALS LTD. SAN JUAN RIVER MINERAL CLAIMS, VICTORIA DIVISION

Dear Sirs,

My name is Robin Rooke and I represent a group of partners who control a major interest in hard rock mines which are a part of 1200 claims in excess of 600 square kilometers. These claims have produced positive assays for Platinum, Palladium, Gallium, Nickel, Cobalt, Gold and Iron. Our claims are strategically placed to cover the magmatic "Hot Spots" and vertical gradient signatures.

Extensive field work has produced excellent results and interest is being shown by the major Canadian and American companies who recently visited the site. The remainder of the claims are controlled by Emerald Field Resources from Ontario, Canada who have recently been involved in an extensive drilling program. It is believed that Emerald Resources is now taking their property public as a result of their exploration.

The properties are located at Port Renfrew on Vancouver Island British Columbia, Canada. There are many other claims, to name a few:

- All claims are accessible by industrial haul roads, 100% access in place.
- Only 100 Km from Victoria on paved roads.
- San Juan Harbor in Port Renfrew is suitable for a deep sea port.
- Negotiations have taken place with various agencies to provide road and deep sea port access.
- Mild winters accommodate year round production.
- The town of Port Renfrew and area provide a ready work force with no remote access problems.
- British Columbia government is favorable to mining exploration.

Three years of extensive field work has produced positive assayed results and geological reports that can be found on the TreGuis.com website. We are pleased to provide our properties for option considerations.

If you are interested in this exceptional property, please contact me at:

Robin Rooke  
(West Coast Flootation Systems Ltd.)

Best regards,  
Robin Rooke

### 1. EXECUTIVE SUMMARY

Tre Guis Minerals Ltd. ("Tre Guis") and associates are owners of mineral claims situated on southwestern Vancouver Island, BC. The Golden 1-8 claims are located north of the San Juan River approximately 75 km northwest of the community of Port Alberni. Block A and Block B "Gold" claims are located south of the San Juan River just east of the community of Port Alberni.

The properties are accessible by an extensive network of logging roads. A year round exploration season, with year round labour, power, supply centers and access to deep sea shipping ports all combine to offer favourable logistic conditions.

The Golden 1-8 claims are underlain by predominantly metamorphosed intrusions, volcanics and sedimentary rocks of the Coast Complex ("WC3"). Mafic intrusions (Diorites) hosted in the WC3 in the vicinity of the Golden claims are supported by the presence of appreciable magnetite and local occurrences of Cu and Au. The Vertical Gradient data suggests significant portions of the Golden claims may be underlain by the favourable diorites and associated ultramafic intrusions. There are anomalous Cu, Ni, Au and Hg RGS anomalies in this area. Historical and recent sampling has returned elevated Cu, Ni, Co, Pt and Pd values. Magmatic Cu-Ni-Co-PGE occurrences are known elsewhere in the Insular Belt where dioritic ultramafic intrusions are hosted in the WC3.

South of the San Juan River, auriferous quartz veins are hosted in meta-sediments of the Leech River Complex. A favourable geologic setting for hosting tensional fault related quartz veins associated with felsic dyke and stockwork is present on the Block A and Block B claims. Gold and arsenopyrite are present in the quartz veins with high values of up to 104.5 g/t Au being reported in historical Assessment work. Historical rock chip sampling has established that numerous samples contain elevated Au and As from the area covered by the claims. RGS samples are present containing strongly anomalous values of up to 800 ppb. Historical placer gold production has taken place "down drainage" from the claims.

Additional exploration programs are warranted for the Tre Guis claims. Exploration programs combining stream sediment sampling, prospecting and rock chip sampling are recommended.
