GEOCHEMICAL REPORT ON THE
EASY, ON, BP AND BW CLAIM GROUPS

92-L-3

Introduction

During the summer of 1970 the Kyuquot Syndicate carried out a geochemical silt sampling and reconnaissance program over part of the Kyuquot Peninsula, Vancouver Island. Indications of mineralization were noted at several localities during the initial stages of this reconnaissance. The Easy, On, BP and BW claim groups were staked to cover these indications and subsequent silt and soil sampling was concentrated on these mineral claims.

The reconnaissance program on the Kyuquot Peninsula generated a total of 1,700 silt samples. Of these, 385 samples were collected on the Easy claim group, 115 samples on the On claim group, 12 samples on the BP group and 12 samples were collected over the BW claim group. In addition, soil samples were collected on a grid pattern over selected portions of the On, BW and BP groups. This detailed sampling produced totals of 94, 70 and 55 soil samples respectively from the On, BP and BW claim groups. All soil and silt samples were analyzed for copper and zinc. Selected samples from the Easy claim group were also analyzed for molybdenum. The geochemical results for the above are plotted on maps 160-70-12 to 17.

LOCATION OF CLAIM GROUPS 'EASY', 'ON', 'BP' & 'BW'
KYUQUOT PENINSULA, VANCOUVER ISLAND, B.C.

Location and Access

The claim groups described in this report are located on the Kyuquot Peninsula, on the west coast of Vancouver Island, 95 miles west of the town of Campbell River. As there is no direct road connection to the Kyuquot Peninsula, access to the properties is by chartered float plane, landing at Easy Inlet, and thence by logging road and trail. Alternatively, access to Easy Inlet can be gained by small boat from the nearby logging settlement at Fair Harbour, a journey of 10 miles. A scheduled float plane service operates daily between Fair Harbour and Tahsis, with connections to Vancouver. The precise locations of the individual claim groups are shown on map 160-70-12.

Method of Survey

Silt samples were collected along all streams draining the mineral claims at intervals of 500 feet. By sampling all recognizable drainage channels, a detailed sampling network was obtained over each claim group. The silt samples were taken from the active stream sediment in the centre of the drainage channel. The samples were immediately placed in water-resistant paper packets on which the following information was recorded: sample number, date, grain-size, colour and organic content of the sample. Sample site locations were recorded on specially prepared topographic base maps at a scale of 1 inch to 1,000 feet.

Detailed soil sampling was subsequently carried out over selected portions of the On, BP and BW mineral claim groups. For the On group

a 4,500 foot base line, aligned N 100°E, was laid out with chain and compass. Perpendicular grid lines were turned off this base line at intervals of 500 feet, and soil samples were collected at intervals of 200 feet along these lines. For the BP claims, a 1,500 foot north-south base line was laid out and perpendicular grid lines turned off at intervals of 200 feet. Soil samples were then collected along these lines at a spacing of 200 feet. In the case of the BW claims, the 800 foot long base line was aligned N100°E and grid lines were turned-off at intervals of 200 feet. The sample spacing along the grid lines on the BW claims was 100 feet.

Soil samples were taken from the B horizon, at a depth of approximately 12 inches using grub hoes. The soil samples were placed in water-resistant paper packets on which the following information was recorded: sample number, line number and footage, date, sampling depth, horizon, colour and moisture content.

All samples were shipped to Vancouver for analysis by the Falconbridge geochemical laboratory.

Laboratory Techniques

The samples were dried in a gas-fired hot air drier and hand screened through 80 mesh standard nylon screens. The minus 80 mesh portion of the dried sample was analyzed for copper and zinc by standard geochemical techniques. In addition, selected samples from the Easy claim group were analyzed for molybdenum using standard geochemical methods.

Copper and zinc were determined by standard atomic absorption techniques, following digestion of the sample for one hour with boiling 10% nitric acid. Molybdenum was determined by fusing 250 m.g. of sample with alkaline flux to render the molybdenum soluble. The fusion was leached with demineralized water and an aliquot of the leach liquor treated with 2.5 percent solution of hydroxylamine hydrochloride in hydrochloric acid and one percent zinc dithiol solution. After shaking to develop the coloured molybdenum complex, the samples were compared with previously prepared standards to obtain the molybdenum concentration.

Geology

The portion of the Kyuquot Peninsula under consideration is underlain chiefly by sedimentary and volcanic rocks of the Bonanza Group. The Lower Bonanza consists predominantly of calcareous sediments, including light and dark limestones and skarns. The Upper Bonanza is predominantly volcanic and includes both intermediate flows and intermediate to acid pyroclastics. The Bonanza Group in this area has a regional east-west strike and dips to the south at angles ranging from 25° to 55°.

In the immediate vicinity of Kashutl Inlet the Bonanza rocks are intruded by a medium-grained syeno-diorite plug. Further west in the vicinity of the Malksope River, the Bonanza sediments are cut by a quartz porphyry minor intrusion. The age relationship between these intrusions is not clear.

The area is transected by the Mahatta Fault, a major north-west trending fault zone.

The Easy claims were sited to cover a zone with widespread but minor chalcopryite and pyrite. Mineralization is associated with quartz veining in both volcanics and sediments.

The On claims were sited to cover an extensive skarn zone containing minor disseminated sphalerite.

The BP claims cover a showing with chalcopryite, hematite and magnetite in a shear zone in dark calcareous sediments. The BW claims were located to cover an exposure of dark green andesite containing minor disseminations and veinlets of chalcopryite.

Results and Interpretation

In interpreting the stream sediment data from the various mineral claim groups the following threshold levels, based on the 1,700 silts collected over the Kyuquot Peninsula, were used:-

	Regional Background	Weakly Anomalous	Anomalous	Range	Mode
Cu	<75	75-150	>150	5-488	20-30
Zn	<150	150-300	>300	10-2160	70-80
Mo	<3	3-4	>4	1-11	<2

The results for the individual claim groups are discussed in turn below.

Easy Group (Map 160-70-13)

Anomalous copper values (up to 448 ppm) are concentrated in the northern portion of the claim group. Values in the southern section are almost all in the regional background concentration range, the exception being a low order anomaly in the south-west, represented by two samples only.

Anomalous zinc values show a broadly similar distribution, with highly anomalous samples (up to 2,160 ppm Zn) concentrated in the northern half of the claim group. As in the case of copper, zinc values in the southern half of the group are almost all in the regional background range. An exception to this is a low order zinc anomaly in the south-west corner of the group.

The molybdenum data show a low order anomaly broadly coincident with the copper and zinc anomalies in the north of the claim group. Molybdenum values in the southern portion of the claim group are entirely in the background range.

On Group (Map 160-70-14 & 15)

The silt data reveal only a low order zinc anomaly (maximum 317 ppm Zn) over the On claim group. The copper content of the silts is entirely in the background range.

The soil grid was sited to cover the inferred extension of the skarn zone which forms the host rock in the initial sphalerite showing. The soil results are not encouraging since only a single sample is anomalous for zinc (349 ppm Zn) and copper values are uniformly low (maximum 30 ppm Cu).

BP Group (Map 160-70-16)

The silt data for the BP claims show background copper and zinc values.

The soil results are not encouraging since only a single sample is weakly anomalous for copper (108 ppm Cu). All other values are in the background concentration range for both copper (maximum 40 ppm Cu) and zinc (maximum 63 ppm Zn).

BW Group (Map 160-70-17)

The silt data for the BW claims show a single weakly anomalous copper value (94 ppm Cu). The remaining silt samples have background copper and zinc contents.

The soil results for the BW grid are not encouraging. A single soil sample has a weakly anomalous copper content (85 ppm Cu), the remaining values being in the background range for both copper and zinc.

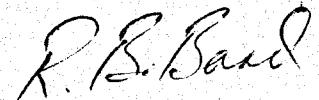

Conclusions and Recommendations

1. On the basis of the geochemical data the Easy claim group appears to have the greatest potential for mineralization. It is recommended that future exploration effort be concentrated on these claims, and that initially particular attention be paid to the area of anomalous copper, zinc and molybdenum outlined in the north of the claim group. A combined soil sampling and detailed prospecting program is recommended in order to evaluate this anomaly.

2. The results for the On, BP and BW claims are not encouraging, and no further geochemical work is recommended on these claims.

April 24, 1971

The Chief Mining Recorder,
Omineca Mining Division,
Smithers, B.C.

Dear Sir:

Re: Statement of Qualification

This is to certify that the geochemical work done on the Easy, On, BP and BW claims was done under my supervision.

The silt sampling program was carried out by McDonald Consultants Ltd., under the direction of Mr. E.D. Dodson. Mr. Dodson is a Professional Engineer registered in the Association of Professional Engineers of the Province of British Columbia and the Yukon Territory.

Mr. K.H. Christensen has been instructed by Falconbridge geochemist, Dr. R.B. Band, in geochemical survey techniques, and is a fully qualified field geochemical operator.

Mr. C. Dyakowski was instructed in the field by Falconbridge geochemical operators, and is qualified as a geochemical sampler.

The analyses and evaluation of the results were done under the direction of Dr. I.L. Elliott, Chief Geochemist, and Dr. R.B. Band, Assistant Geochemist for Falconbridge Nickel Mines Limited. Doctors Elliott and Band received their Doctorates from the Royal School of Mines, Imperial College, London, England.

Yours very truly,

FALCONBRIDGE NICKEL MINES LIMITED
