# DRILL RESULTS, 1981 WINDY - CRAGGY PN 135

#### FORWARD

During the short 1981 field season the first stage of a proposed two stage drilling programme on the Windy - Craggy massive sulphide deposit in northwestern B. C. was completed.\* Basic assay data is finally available and is presented in this report, accompanied by a map folio.

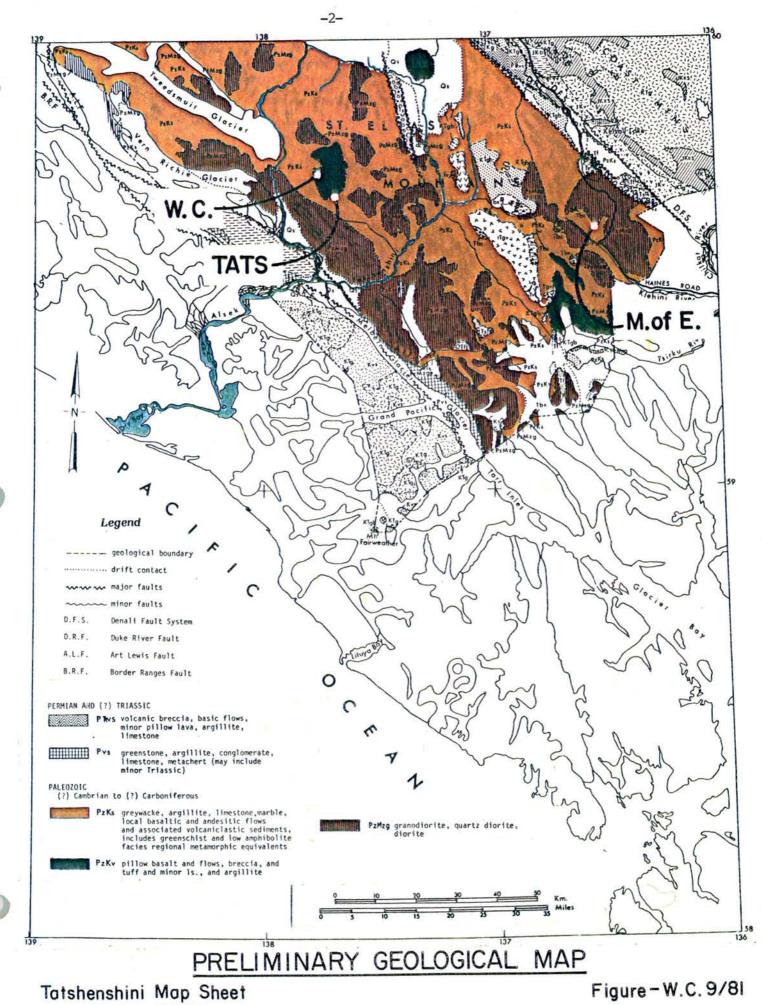

Data required for a complete assessment of the 1981 work has not been received as of this date (Jan. 21) although reportedly shipped from the Whitehorse assay labs in mid December. Many delays were expected considering the late date at which authority to proceed with the programme was received.

An inclusive summary report will be prepared within the next couple months. Included will be 1) Petrographic study of select specimens so that rock units can be correctly labelled. (2) Check assays including fire assay reruns of presently AA - determined gold and silver (i.e. the size of sample used may be critical). A shipment of rejects from the Whitehorse assayers is awaited. (3) A study of trends (zoning, alteration, etc) within the deposit, including more accurate locational plotting of geophysical data. (4) More detailed plans for property exploration, dependant on any escalation of scope.

The physical and historical aspects of Windy - Craggy were adequately described in the February, 1981 Report and will not be repeated here.

#### ABSTRACT, DISCUSSION AND CONCLUSIONS

#### I ABSTRACT

First and second stage programmes were designed to test-drill the largely unexposed deposit for continuity, including depth, along a relatively accessible 3000 feet of minimal strike length. The first stage, 10 drill holes totalling 2540.96 metres (8336.48 feet), successfully outlined the southern portion of the deposit within broad parameters along a strike length of 400 metres (1312.3 feet), and indicated mineralization to extend to depths of at least 492 metres (1614 feet).

#### II DISCUSSION OF RESULTS

#### A Drilling

#### 1) Historical and Chronological

Two new Longyear Drills (FLY 38's) were utilized by Longyear Canada on the job. Due to the lateness of the season, there was no chance to properly appraise the job before hand, and our 1965 experience (BBS1 - AQ drill holes) was used as the sole guide. A John Deere 450 tractor was flown to the property for drill moves, etc. Crews were based at Tats Lake and flown to the property daily using a Bell 206B chartered from Pacific Helicopters. Heavier helicopter hauls were made by Shirley Helicopters of Whitehorse.

2) Drill Holes

Drill holes were located as close to section as possible. Locations are shown on Map 034-81-A (in pocket). It is to be noted that this is an updated version of earlier map Figure 2, 034/80 which should now be discarded. Co-ordinates were assigned to a 500 m. grid oriented True North. As drill equipment is still not in metric, core was logged in 'feet and inches'. All ground measurements not affecting the drill directly are in metric. In most cases any significant numbers are shown in both systems.

Holes were dip-tested using etch tubes. Such tests were not carried out on occasion due holes blocked at depth. Tropari tests for bearing proved unreliable due magnetics.

#### 3) Core Logging and Sampling Procedures

Although the writer did most of the organizing of the Windy - Craggy project, geological help was required and geologist Don Hoy was obtained thru G. A. Noel, Consultants.

All core <u>showing more</u> than 5% sulphides was split and assayed. After being preliminarily logged on the property and flown to Tats Lake for detailed logging,drill core was split by a power splitter at the Maid of Erin camp where it is now stored.

Attempts were made to sample at 10 foot intervals except where obvious changes in character were noticed. As several tons of sample was involved, and we had experienced problems with CPA to Vancouver in the past, it was decided to utilize <u>Bondar - Clegg in</u> <u>Whitehorse</u> following confirmation of their ability by known Bondar -Clegg officials in Vancouver. However, as shown on the logs, we are still missing a few samples.

#### 4) Assay Procedures

To date check assays have not been made but we have little reason to suspect number problems with Bondar - Clegg, Whitehorse. Normal waiting time for assays in Vancouver increased from 5 to 6 weeks in 1981 due to heavy geochemical demands. All assaying was done in Whitehorse except for sulphur which was done by Bondar - Clegg in Vancouver. Gold, silver, lead and zinc were done geochemically (AA). Some goldsilvers will be checked by fire assay methods. Sulphur is shown in the logs as "sulphide  $(S_2)$ " - a close approximation being that pyrrhotite, the dominant sulphide, contains about 40% sulphur and the only other sulphides, pyrite and chalcopyrite, would not significantly change this generalization more than a percent or two, which is unimportant at this stage.

Assays are presented in the drill logs enclosed and are plotted on accompanying assay sections. Cobalt, copper, sulphur, and any anomalous value in pm's or zinc, are included in individual or composite form. Transparent overlays (folios only) contain the copper-cobalt sulphide values and the underlays contain the general geology. Summaries and averages are presented at the end of each drill log.

B Assays

1) Value Distribution

Copper distribution within the deposit is such that copper-rich segregations may occur, especially to the north where the closest drill hole encountered the best continuous copper section to date, 566 ft of 2.6% Cu within a 107 foot core length in which 40 feet of similarly logged material is still to be reported on by the assayer. This was part of a sulphide bearing zone whose core length of 967 ft. (238 m) represents a true width exceeding 700 feet which averages 0.78% copper. Copper vs sulphide plots diverge considerably from straight lines. Fig. 19-81 (a&b) represents an attempt to contour average copper and sulphide values projected to surface, the purpose being to suggest trends, etc.

Assay summaries, including averages, are included with the drill logs.

-5-

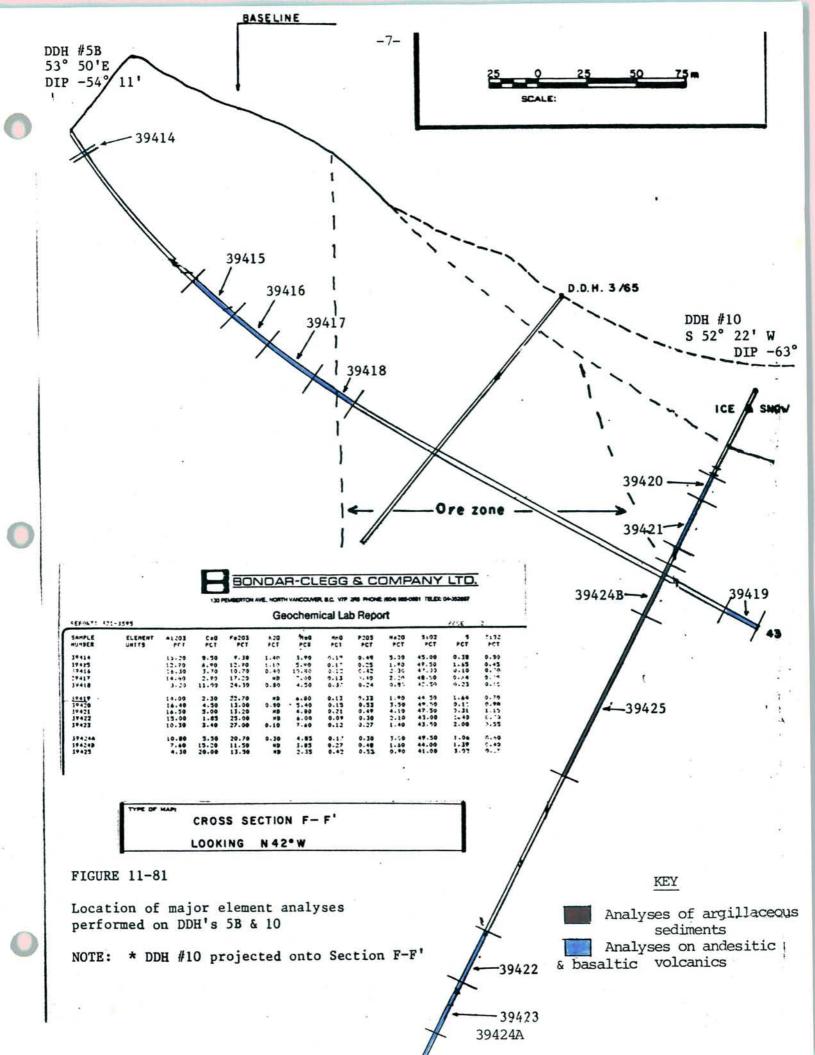

All sulphides encountered, with the possible exception of pyrite in shale, and the probable exception of chalcopyrite, are cobaltiferous with approximate uniform or straight line Co/S ratios. The highest cobalt assays of 0.23% occurs in 83% sulphide material (0.5 % copper) suggesting a maximum of 0.28% Co in pure pyrrhotite. This number is slightly lower than that suggested by earlier microprobe work. The distribution of cobalt in pyrite vs that in pyrrhotite in the drill core is not known at this time. A cobalt vs sulphide plot will be available for study at a later date.

<u>Gold-silver content</u> is minimal but assayable. The best average of 355 ppb Au occurs in the better copper sections of hole #5b. Checks will be made as earlier sampled material, tested by fire assay, suggested an erratic but higher pm content, especially of silver. Pm values in this range would be more accurately determined in a chalcopyrite concentrate.

Zinc content in the main zone is so low (maximum 900 ppm over 35 feet in hole 5(b)), that copper-zinc ratios utilized in any zoning studies would be hardly valid. Zinc in adjoining shales (DDH #3)reached 1275 ppm across 100 feet. Sphalerite associated with a siliceous breccia is present in one section and perhaps a detailed but very local examination (planned) may suggest an orderly rather than haphazard arrangement not recognized during logging. Siliceous volcanic float containing sphalerite and galena is known elsewhere, including the Tats - Kowall area (Map WC9/81).

The value of rock geochemistry is in doubt as the area sampled (1000 feet across the deposit) is within the central aureole of the deposit itself, (Fig. 11/81). Sampling should be carried out across several thousand feet, but this is difficult due to topography. Erratic values (i.e. Na) appear across the deposit as sampled such as to suggest lack of recognizable orderly depletion or enrichment, but a detailed study may shed more light on this.

\* All elements in ppm 6 Samples taken Sept 13/81 along 100 feet of Creek
\*\* Some sediment included??

Water analyses (Red Creek) are interesting, (Table 12/81) confirming that it should not be drunk by humans. Metal content is highly anomalous save for silver which is below detectable levels.

2) Geological Interpretation

a) Orientation

The Geological Sections will be further defined at a later date; to this point no trouble has been experienced in locating the sulphide zone utilizing more than a simple interpretation of geology. The western contact of the sulphide zone was accurately predicted in all holes to within a few feet of it's intersected location. The totally unexposed eastern contact is more of an unknown. Attitudes suggest that, although the western contact (fault controlled in part) is near vertical, some of the massive sulphides (+70% S2) occur as easterly dipping lenses (?) within the zone. Due to lack of holes and penetration, plus faulting, the attitude of the Fastern Contact is uncertain. Thus we do not know at this time what is "hangingwall" and what is "footwall". Regional observations on the Windy Claims suggest a steep easterly dip while those on the Craggy suggest a vertical to steep westerly dip. The writer is unprepared to be committed at this stage. It appears that plunging sulphide shoots are likely but evidence is again too skimpy for support.

b) Rock Types

Cross sections suggest, as earlier described, that rocks to the west of the sulphide zone consist of felsitic to slightly basic volcanics (andesites) interbedded with shales (some are prominently calcareous and may serve as marker horizons). The southern sulphide zone consists of at least three steeply dipping, paralleling bands. These may merge into a single unit to the north. Rocks to the east of the sulphides are dark chloritized volcanics (andeso-basalts) succeeded by a dense black shale and/or argillite unit at least several hundred feet thick. Alernating bands of volcanics and shales (argillite?) are evident at the first exposures beyond the ice cap 1000 feet to the east.

-9-

Utilizing the Anyox Model (see earlier diccussions) either contact would qualify as "footwall" at this stage. Alteration appears to be Lower Greenschist.

#### c) Sulphide Zone

The <u>sulphide zone</u> consists of the often described massive sulphides (+50% pyrrhotite, minor pyrite and chalcopyrite) flanked by "stringer-zone" mineralization ( $\pm$ 30% S<sub>2</sub>). 1981 drilling showed extensive "crackle"or weakly brecciated zones containing higher than usual chalcopyrite/pyrrhotite ratios. Sulphide persists through depths of at least 1500 feet (Photo 8/71).

#### d) Anomalous Geological Features

Based on west (footwall??) geology, and observation of the sections (i.e. model photographs enclosed, Sect. C-C' + 40N & Photo 6) it appears that DDH #10 did not penetrate the main zone as intended (it was hoped that hole would flatten) before being abandonned due to freeze-up. Faulting present may have caused complications. This hole collared in ice and can not be re-entered, one problem with ice cap drilling.

Some problems were encountered with <u>cavities</u> of large dimensions and no surface representation - i.e. DDH's 2/81and #1(65). Pyrrhotite present prior to encountering the cavity oxidized rapidly, some visually within one hour of pulling, and the writer interprets the cause of the large cavity to be due to "burning", (rapid oxidization), of similar material. Deeper holes showed no sign of this phenomena (see sections).

A breccia-like rock encountered under the snow cap (DDH #8 & #10) is suggestive of some form of laharic breccia. Fragments are unlike those composing rocks exposed on surface, and the matrix seems more tuffaceous than would be expected on a normal mudslide or in a derived calcrete. The breccia is deeply weathered in part but is

-10-

unmineralized save for secondary oxides. In the two best exposures, the breccia overlies unmineralized volcanics but at a low dip angle. The origin is in doubt at this time.

e) Shape of Deposit

In general it would appear that the Windy - Craggy deposit has the shape of a crater with tangents or offshoots to the north and south. 1982 drilling should clarify this.

1

### f) North Extensions

No sampling was done on the north extension, in fact it was not even visited during 1981. Float from the north cliffs, where a steep sulphide body is exposed, (see Model, Photo 5/81) was sampled along a two mile moraine. Copper assays (Table 13/81) are erratic as in previous sampling but the cobalt content, also erratic, must be compared to total sulphides, assays (the material is decidedly more pyritic) for which are awaited. When sulphur assays are completed on other mineralized material, ratios may suggest regional trends.

g) Geophysical Surveys

Airborne DIGHEM traverses have proven very difficult to plot due to the lack of ground control, the "ground" in <u>the area</u> of most interest being essentially impassable. Unfortunately the only airphotos available and used for plotting suffer from distortions and severe shadow effects in the area of interest, (Fig. 17/81). Also the snow was much further melted when the photos were taken than when DIGHEM photographed during their traverses. <u>Detailed</u> studies by the writer, after constructing a 35mm viewer, suggested that only minor changes in the DIGHEM plot are necessary. In order to utilize all the data, we should make a few airborne obliques about the same time of the year that DIGHEM flew. Ice fracture patterns identified at low level on the DIGHEM photos could be useful as these change little from year to year.

# TABLE 13 - 81

46034	0.07	0.042	
46035	0.87	0.067	

\* Analyses for Sulphides not yet received.

1

There is also a possible plotting problem due to the varying and non-lineal number of frames between fiducial marks, apparently an effect caused by the helicopter slowing down in precipitous situations, but cameras continuing at the same speed.

Several sets of prints of anomalous locations will be made off the DIGHEM film roll, and the results discussed in more detail. Dighem Reports and Maps (5) have been forwarded to Toronto. Assuming DIGHEM plots correct, the centre of the

Windy - Craggy EM anomaly on Line 105 is 1000 feet east of the only usable drill set-up, thus the footage allowance to guarantee complete penetration of the zone (DDH #9 or #9+100m N?) would be at least 1400 feet. A shallow hole (less than  $-45^{\circ}$ ) would run the likelihood of encountering huge cavities (such as DDH #2 and #1/65) and a steep one would never reach the zone within the capability of the drill without wedging.

#### III CONCLUSIONS

Despite many problems due to the pioneering aspect of the project, first stage drilling was successful in outlining the southern portion (1/3?) of the massive sulphide deposit. The main north center of the large body, it's presence now better confirmed by airborne geophysics, remains to be tested in 1982 as per earlier recommendations. Initial plans were to work outwards from this more northern location in 1981, but circumstances forced most early work southerly. Snow drilling was only moderately successful due to crevasses and appears doubtful for 1982. Thus the longer, more expensive alternative holes from the ridge top are required unless intermediate set-ups can be constructed (given low snowfall).

-13-

### IV PROPERTY SITUATION

The Windy - Craggy claims have 5 years additional assessment applied to them (Figure 15/81).

V RECOMMENDATIONS

ı

It is recommended that drilling proceed as initially planned, with modifications as dictated by circumstances yet unforeseen. Details are discussed under the <u>1982 Budget Section</u> which follows.

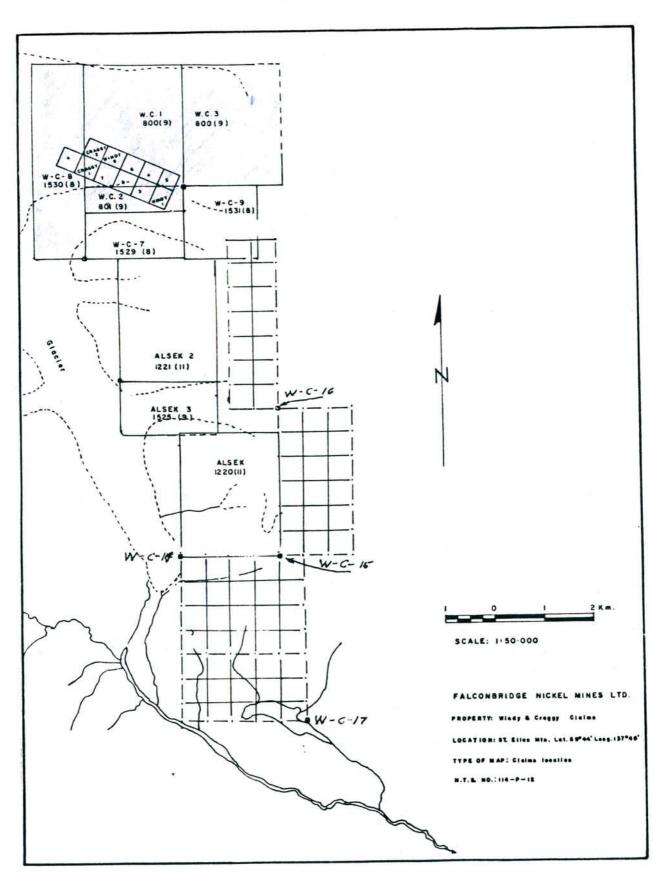

Figure 15-81: Windy & Craggy Claims January (82)

C

,

-16-

#### 1982 BUDGET

Budget proposals are presented under two headings, a) Current and b) Additional.

a) Current

Approximately \$ 600,000.00 remains of the 1,500,000.00 budget originally planned. The best possible cost estimating can be done by simple reference to 1981 costs. Certain cost items will not occur again but others, such as mobilization on completion of the program must be considered. Costs of some items involved in any expanded program are also presented.

Overall project costs in 1981 worked out to about \$100/foot. The only items which will be reduced significantly in 1982 will be infrastructure (camp, etc.) and excessive fuel hauls by helicopter. During the past season these items totalled about \$150,000.00. Deducting them, 1982 costs should then be about \$83/ft. With inflation increase, a \$90/foot figure should be used. Implimentation of new drilling techniques - drilling mud, water heaters, NQ rod for initial drilling, and fewer set-ups but longer holes - should reduce costs to about \$80/ft, but a larger helicopter will be required for moves in a more difficult terrain. The safest estimate then works out to about \$85/ft overall, allowing about 7000 feet of drilling for the \$600,000.00 available.

Items in addition to those required in 1981 should include:

1) Larger project <u>helicopter</u> - a Long Ranger will cost more but this will be offset by more efficient crew moves and better lifting capability at altitude - Cost Diff. - 0.

2) A better <u>communication set-up</u> between crews, helicopter and Northern Telephone. This is a safety requirement which should add considerable efficiency as well. A VHF system, totally recoverable, has been designed similar to others in use in the St. Elias - Cost \$12,000.00.

-17-

3) Expanded <u>mapping</u> of the Windy - Craggy Deposit and <u>legal</u> but minimal claim surveying (i.e. W. C. #1, 2, 3 and 9) - Preliminary estimate (McElhanney - \$10,000).

4) Expanded DIGHEM Survey including better definition of the Windy-Craggy Deposit \$20,000 (should be done along with the Tats Deposit). The job and price depend on the availability of DIGHEM in the area - i.e. they may be working nearby in Alaska. The remainder left in the fund applicable against comparative drilling costs would then be 558,000, which would allow 6550 feet of drilling.

b) Drilling Plans - 1982

No changes are anticipated in the grid drilling program set up in 1981 which includes drilling on sections G to L, (Table 16/81). Snow drilling from the east would increase efficiency but we can not rely on such at this time, thus drilling will have to be done from the ridge top. As outlined on Map 034/81 (a) (pocket), a short 500 ft.

drill hole should be put in from a convenient set-up on Section A, which can be occupied earlier. This hole, #11, would test any plunge of the sulphide body to the south and may help explain the sudden termination evident on surface, or the weak DIGHEM response (Figure 17/81). Priority would be lower than that of the other holes, however.

The length of Hole #9 (Section G-C') must be doubled (600 feet remaining). Some consideration will be given to induced flattening by wedging on all subsequent steep holes.

Drill Hole #12 will be on Section H (1300 ft), #13 on Section I-I' (1400 ft), and #14 on Section J-J' (1500 ft). Footage remaining (1250 ft) to arrive at a total of 6550 ft (1996.4 m) should be allocated to Section K-K', L-L' or M-M' (if feasible). These lengths would be minimal and unless holes flatten may have to be extended.

The above program will minimally test what the writer has always believed to be the largest part of the W. C. deposit, a concept enhanced in 1981 by the extremely high E.M. and accompanying magnetics

TOTAL 1996.44 m. (6550 ft)

encountered by airborne work. We can not affort gambles on such as deep surface (?) cavities encountered in DDH #4, thus the holes should be steep enough to miss these problems. Each set-up will be rationed to only one hole. Unless other financing arrangements can be made, it being more important to prove continuity along strike that at depth. Continuity of the sulphide body will be proven by intersections but little will be gained as to continuation or configuration at depth. The most northerly hole envisioned (on Section L-L' or M-M') will air in the direction of the massive sulphide evident on the inaccessible north (Craggy) cliffs. The outcrop will be geographically positioned by helicoptercontrolled transit surveys. The intervening ground, although devoid of massive sulphides, is mineralized to some degree over impressive widths (1958 observations).

c) <u>Budget Summary</u> - Second Stage (minimal requirements to mount worthwhile program). This is presented on form #4.

d) Timing and Distribution

Jan.	Supervision, Communications System and Warehouse overhauls and preparation	\$ 10,000.00

March, Apri	l & May (as Jan.)	30,000.00
June	As Jan., plus mobilization	30,000.00
July	Drilling - as 1981	100,000.00
August	Drilling — as 1981	150,000.00
Sept.	Drilling, Demobilization	100,000.00
OctDec.	Supervision, Assays, Report	80,000.00

TOTAL

\$600,000.00

e) Third Stage Program - 1982 (for reference only - not budgeted for at this time).

#### A) Moderate Expenditures

1) 2)	total) plus two extra holes from established set-ups (3000 ft) = 4000 feet @ \$50/ft (estimate overall average \$70/ft*)	\$200,000 15,000
3) 4)		15,000 20,000
	TOTAL	\$250,000
e)	B) <u>Heavier Expenditures</u> (1981 Range - for reference only)	
1) 2)	As (A) on previous page Additional drilling, north end. Would include oblique (off-section) holes for a flatter intersection, or crevass	250,000
3)	bridging (metal mesh) from ice cap: 2000 ft @ \$90/ft (see map 034/81(a)) if larger helicopter available. Cat road access to establish winter road route to Tats Lake. 42 miles @ \$15,000 mi. Haulage road costs (to Tats	180,000
	Lake only) estimated at \$40,000/mi, plus \$150,000 for bridges, culverts, etc.Bridge Costs including pile driving are about \$1000/ft	630,000
	TOTAL	\$1,060,000

\$1,060,000

f) Comment on Second Stage Program

This program is essentially set up and only modifications are required for it's implementation.

> Some early committments are required, however. These

include:

1) A committment to Longyear so they can 1) begin construction during the off-season of special design water heaters and 2) decide on drill deployment - i.e. if we're not proceeding, they want their drills back. The same holds for D. J. Drilling's J. D. Tractor.

2) A committment to construct the VHF mobile terminal - lead time 5 months due to uncertainty of part procurement.

3) Arrangement for 1982 field help.

4) Fuel haul arrangements while snow conditions are suitable (Feb.) 5) Helicopter Arrangements (there were no established company machines left available as of March, 1981). We will look hard at Pacific again, providing the correct pilot and machine are available. A 206  $L_2$  model (latest with larger engine) would be the most suitable.

q) Comment on Third Stage

This would involve more extensive work on the Windy Craggy deposit.

Examination in December, 1981, of routes to Tats Lake (J. J. McDougall, Grant Stewart, J. Hugi) suggested that the best winter access would be from the Carmine (Red Mtn) airstrip across the lower O'Connor and up the south side of Tat Creek (see Map 114P in Folio). Work involved can only be properly estimated in the summer when overburden, etc. can be examined. A cat could probably walk thru in about 2 weeks, preparing a later winter cat train route. This would anticipate an expanded project in 1983. Other routes - i.e. Henshi Creek (E. Arm) seem a distant second choice at this time due to the roughness of the glacier, although the base of the East Arm glacier could be reached easier than could Tats Lake.

Tats Glacier would present about a mile of tough going for a large cat before it smoothens out, but there is more room to manoeuvere than on the East Arm. Ultimate access to the deposit (i.e. possible adit) appears much better off Tats Glacier unless a roadway can be blasted in solid rock to the camp on a bench 200 feet above. An adit would be collared off the edge of the glacier below the Red Creek camp but snow accumulations would have to be allowed for at the portal i.e. a 50 foot(?) shed elevated by fill on the glacier would be a minimal requirement. Waste rock would conceivably supplement the natural and extensive gravel moraines forming a solid and elevated roadbed which should move so slowly as to be hardly troublesome. The one mile above the base of the Glacier would be most difficult, requiring heavy equipment and gravel to fill numerous ice depressions . However, once in, this route would be free of dangerous crevasses or avalanches. Contractors will not estimate beyond Tats Lake until the area is ground examined.

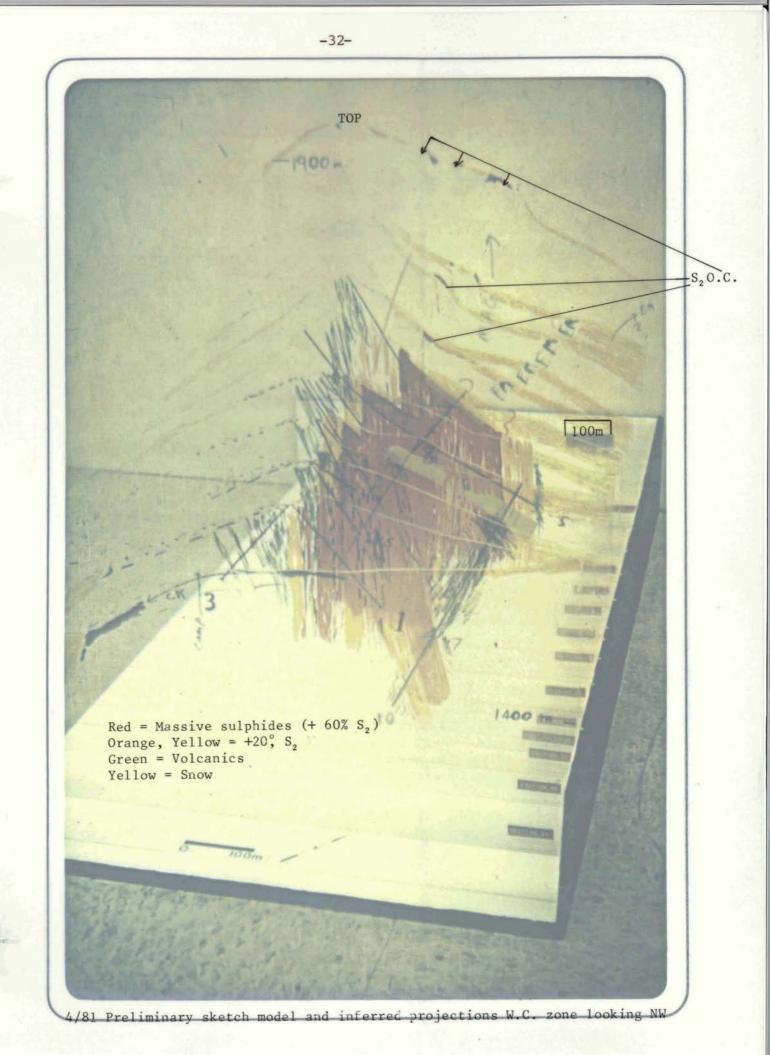

Further comment on possible additional stages is not practical at this time.

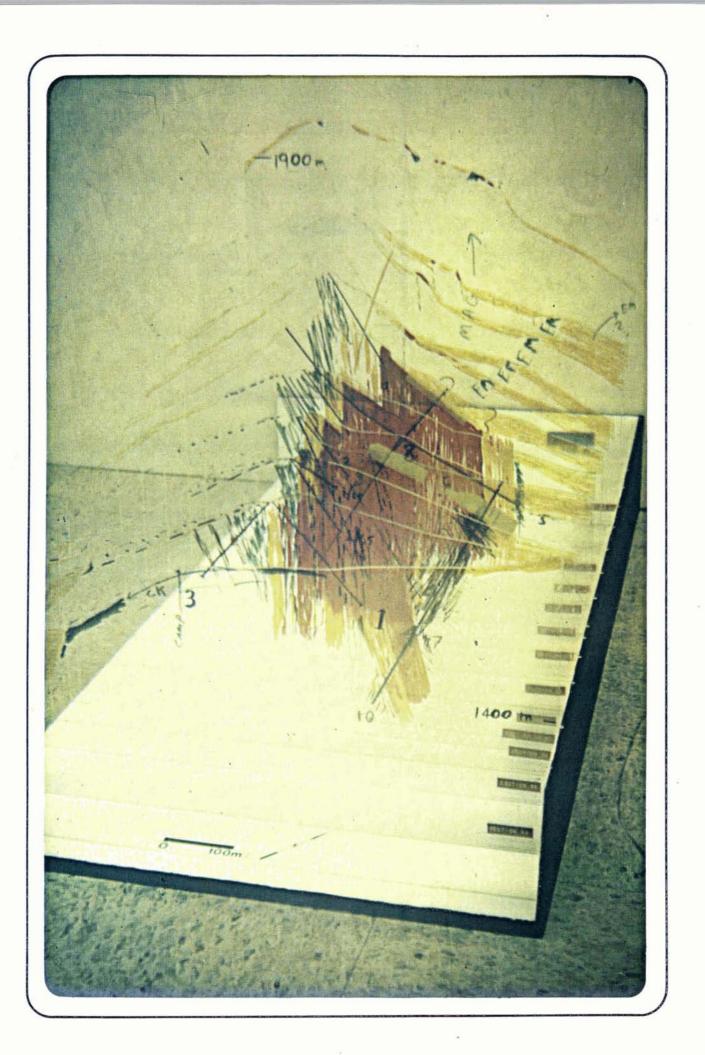

Jan Insluge

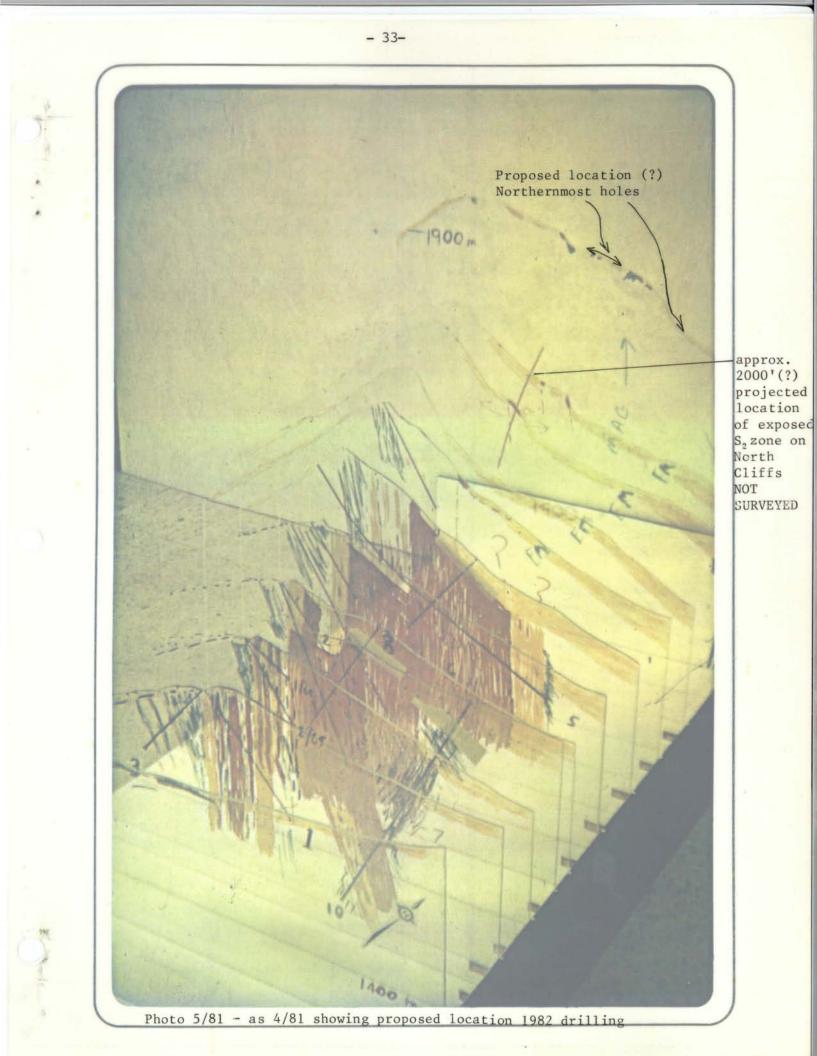

APPENDIX 1

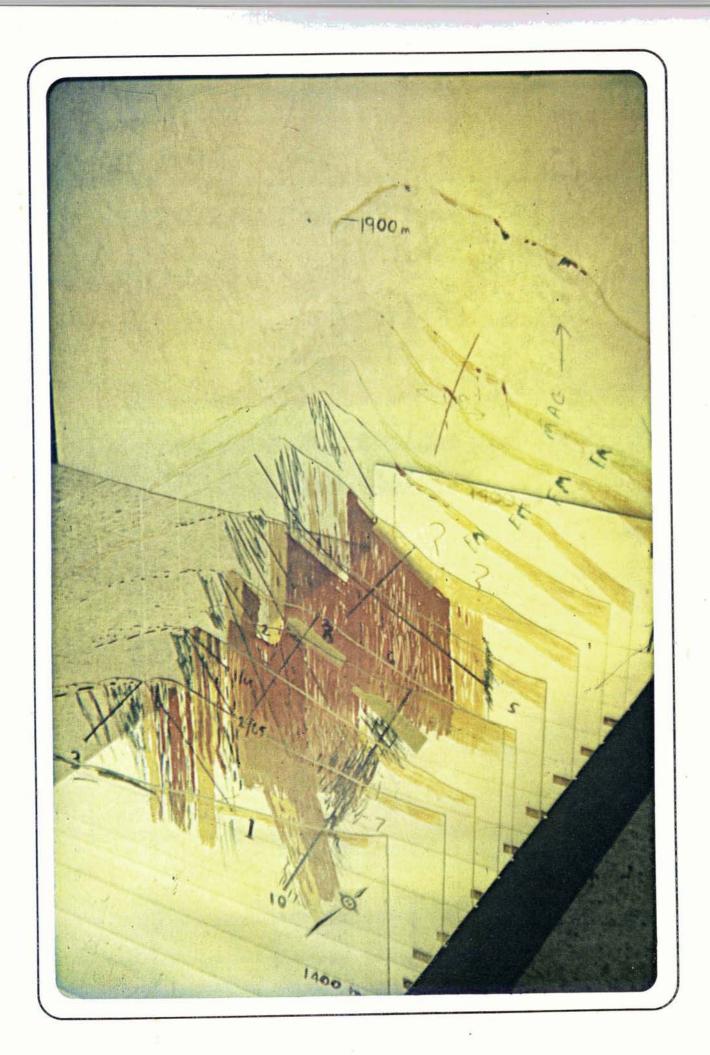

Photos

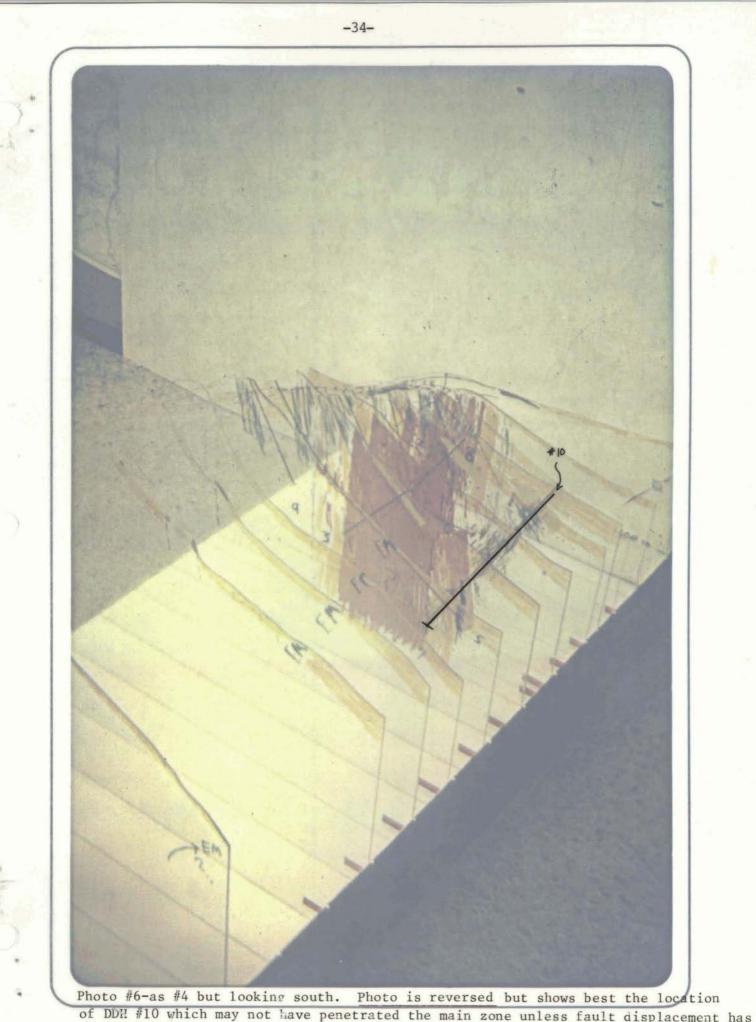

۲

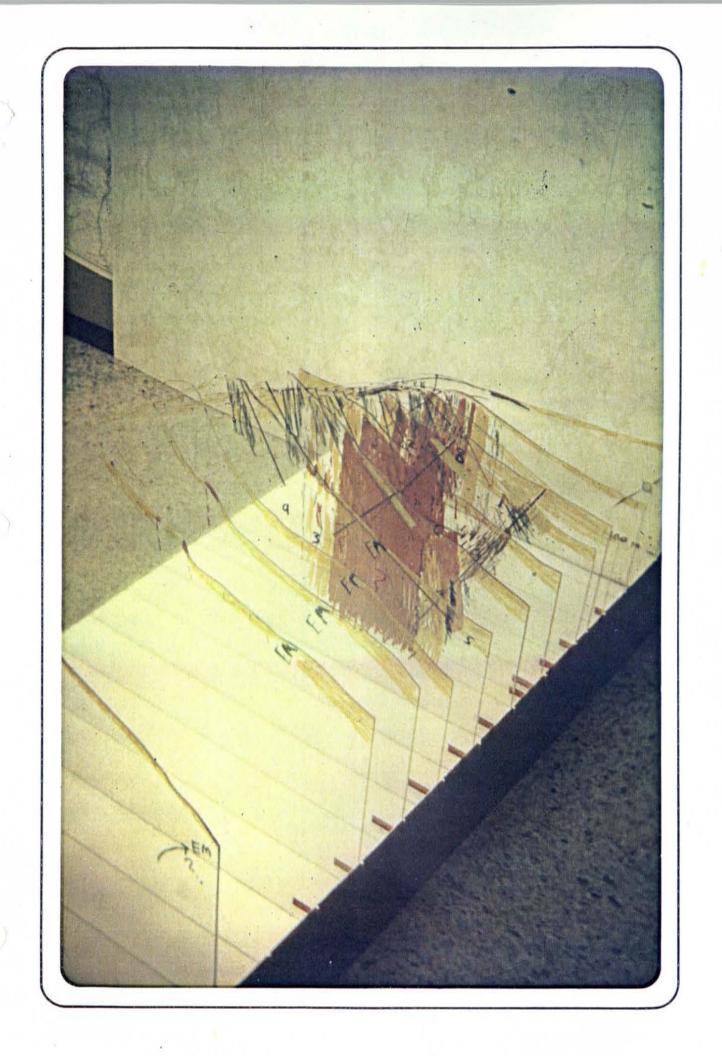

of DDH #10 which may not have penetrated the main zone unless fault displacement has occured.

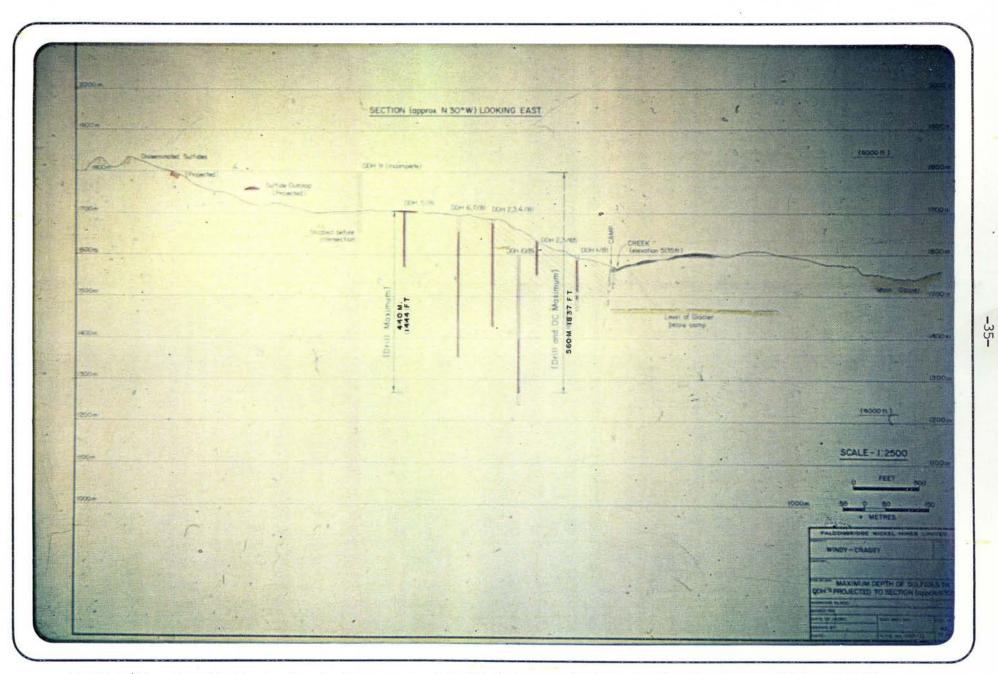

Photo 7/81 - Longitudival view looking east of drill holes projected showing depths at which sulphide was encountered. NOTE: LEVEL OF GLACIER

APPENDIX 2

Diamond Drill Logs

## LEGEND

- A Massive sulphides (50-100%), pyrrhotite, pyrite, chalcopyrite.
- B Sulphides (10-50%), pyrrhotite, pyrite, chalcopyrite largely as stringers, bands & patchy mineralization.
- C Sulphides (0-10%), pyrrhotite, pyrite, chalcopyrite as disseminations, vein & fracture fillings.
- D Rusty gossan-highly oxidized.
- 1 | Relatively unaltered basic-intermediate flows, sills & dykes (andesitic)
- 2 Schistose fine grained basic volcanics, pillow lavas, chlorite & epidote alteration (spilitic basalts?) commonly interbedded with chert & argillite.
- 3 Relatively unaltered medium to coarse grained basic-ultrabasic intrusives (dioritic gabbroic?).
- 4 Felsic dykes, light grey, medium grained.
- 5 Black shale, laminated, aften argillaceous & calcareous.
- 6 Argillite, black, thinly bedded & massive, commonly calcareous & pyritic.
- 7 Undivided minor metasediments & metavolcanics, thinly bedded.
- 8 Light grey to black limestone, argillaceous.
- 9 Dark green to grey chert, commonly chloritic, resembles fine grained rhyolitic volcanics in places.
- 10 Volcanic breccia-conglomerate, subangular foreign clastics, tuffaceous matrix (laharic breccia).
