SUMMARY REPORT  
on  
**Discovery 1**  
N.T.S. 92 J/3  
by  
Les Demczuk M.Sc.  
January 1987

TARGETS:

The subject property is located approximately 3km south of the Northair Mine, an important gold, silver and base metal producer. The main rock types are similar to those on the Northair property and southerly striking quartz-carbonate veins (Northair ores lie in quartz-carbonate veins) indicate the possibility of an extention of this deposit to the Discovery 1 claims.

*and Discovery 2*  
LOCATION ACCESS and MINING/DIVISION:

The Discovery 1 claims are located in the Vancouver Mining Division, 10km southeast of the ski-resort of Whistler, and 100 km north of Vancouver, B.C.

Access to the property is by a good secondary grave logging road, off the main Vancouver-Whistler highway, which tends northward up Callaghan Creek and intersects the Discovery 1 claims.

<sup>28</sup> The property consists of a 4 post (LCP) claim totaling 16 units. The claim was staked on October 26, 1986 and April 5, 1987 is registered in the name of Les Demczuk record no. 2011 and 2106

REGIONAL and LOCAL GEOLOGY:

The Discovery 1 claim group is a part of the Alta Lake - Callaghan Creek area of the Coast Plutonic Complex. Strata of the Alta Lake Pendant from a northwest trending belt of metamorphic rocks are bounded by quartz-diorite and diorite. The pendant rocks are dominately intermediate volcanics, volcanic breccias, tuffs and sandstone with minor amounts of argillite and limestone. The rocks are of Cretaceous age and have been metamorphosed to greenschist facias characterized by actinolite epidote, zoisite, chlorite, boitite and albite. The cleavage strikes north-northwest and dips steeply.

The Northair gold mine lies 3km to the north of the Discovery 1 claim group and approximately 6km north of the Callaghan Creek Basalts. The mine is hosted by Cretaceous rocks of the Alta Lake Pendant Strata with the greatest mineralization occurring in the steeply dipping quartz-carbonate veins.

Galena, sphalerite, chalcopyrite, pyrite, gold and argentite exist in these vein zones. Core samples containing large, irregular crystals of sphalerite, galena, and chalcopyrite indicate that the ore deposit might be of hydrothermal origin. The Discovery 1 claim group is located approximately 3km down the strike from the Northair auriferous veins in similar rock type and structure. A brief geological reconnaissance survey conducted in April 1980 on Disk Claim group (presently Discovery 1) by Crack Resources Ltd. revealed evidence for the potential of significant mineralization. Various types of wall-rock alteration associated with epigenetic gold deposits were observed near fracture zones on the property. Carbonatization the formation of secondary carbonates, takes place in the phyllites and extends for several meters on the west fracture zone. This is particularly significant because it lies along the approximate strike of the gold bearing quartz-carbonate veins only 3km to the north. Copper and iron staining, often indicative of gold is abundant in the shere zones. Chalcopyrite, argintine, and gold exist on surface outcrops. Grab samples taken from these exposures in 1980 yielded 0.66 oz/t silver 0.004 oz/t gold and up to 1-2% copper.

WORK SUMMARY:

and May 5, July 20, 21 1987  
on Discovery 2

The work program was conducted on Discovery 1 property by Les Demczuk on October 26, 28 and November 15. It included prospecting and collecting rock and silt samples. As a result of this program main types of rocks were identified and mineralized zones were located on the north and east part of the property. Geochemical results with highest values Ag74.8 ppm (2.1oz/t) Cu 55720 ppm (5.5%) and Au 1150 ppb (0.03oz/t). Appearance of wall-rock alteration, Cu and iron oxide staining on surface outcrops and surface extent of quarts carbonate veins establish promising evidence for potentially significant mineralization in the Discovery 1 claim.

RECOMMENDED WORK PROGRAM:

Initially, geological mapping and prospecting is needed on all property. A rock and soil sampling program is recommended on selected areas.

A second phase of exploration should include induced polarization surveys, trenching and diamond drilling on selected targets. Estimated start date of the program is July 1987.

Respectfully submitted

Les Demczuk M.Sc.
