SUMMARY

- (1) A program of BQ drilling totalling 761 meters in 6 holes was completed on the CRESCENT Claims between September 20 to October 18, 1980. Results were received in early November indicating several slightly anomalous zones over significant widths. However, in general, values are far below potential ore grade with isolated highs of up to 0.226 oz/ton. A proposal for drilling in 1981 is submitted.
- (2) A short reconnaissance prospecting program was conducted from September 5 to 17th in the area between Atlin and Dease Lake.
 A 15 unit claim was located on Pillman Creek near Atlin Lake which is in Atlin Park.
 A significant silver anomaly was found near Heart Peaks in the Sheslay River Area.
- (3) A total of \$6,300.00 assessment work was filed on the EASY Group with one year applied on EASY THREE, 2 years on EASY TWO and 3 years on TOO EASY. An assessment report has been submitted to Victoria. No additional work is anticipated due to the failure of soil and rock sampling to outline anomalous zones. An area of silicified limestone and quartz eye porphyry near Km 11.5 on the Ououkinish Mainline warrants investigation.
- (4) Sampling and prospecting from two camps on Brooks Peninsula did not indicate any areas of immediate follow up potential.
- (5) Results for limited work done on King Island on the KING Claims were all uniformly low. Surrounding areas deserve detail prospecting.

SUMMARY continued

- (6) A summary report has been written on the Golden Eagle and copies sent to J. Stoochnow. Ownership of these claims should be simplified to expedite evaluation of this interesting area.
- (7) Field work in the Kennedy Lake Area of south-western Vancouver Island failed to encounter any anomalous results. More prospecting is recommended.
- (8) Budget estimates for work recommended for 1981 on properties other than CRESCENT are discussed.
- (9) Assessment Reports are presently in the final stages of preparation on SWAN CLAIMS, LOCKEPORT CLAIMS, SINGA CLAIMS, and HAWKS NEST GROUP.

INTRODUCTION

In September and October a short reconnaissance prospecting program was conducted in the Atlin-Tulsequah region and 761 meters of diamond drilling was completed on the CRESCENT Claims. An assessment report was submitted for the TAR Group as stated in the August Monthly Report.

A fifteen unit modified grid claim, PILLMAN ONE, was located on Pillman Creek near Atlin Lake to cover a reported Tertiary gabbroic intrusion cutting Jurassic Laberge Group coarse clastics with related Tertiary acid volcanics exposed 2000 meters east. Pillman creek has a history of very fine placer gold recovery from the early part of the century. However the Pillman Claim is well within Atlin Park.

Significant silver values up to 12 ppm Ag were found in soils near Heart Peaks, Sheslay River Area. These soils are underlain by rhyolitic and trachytic lavas,tuffs, and breccias that weather to bright hues of red, yellow and orange. Quartz stringers and quartz lined vugs are locally abundant.

This report has been delayed to permit a preliminary evaluation of assay results on the CRESCENT Claims. In general, most of the anomalous results are far below potential ore grade. Higher assays were only found over narrow widths. A variety of gold bearing lithologies gies are apparent ranging from Quartz Diorite Porphyry, Quartz veins, sulfide rich Rhyolite, Rhyolite Breccia to Leucogabbro-feldspar porphyry. Several rock types display geochemically anomalous content of gold over significant lengths such as the dacitic lapilli tuff in holes 1 to 4 and melanogabbro in hole 5. One of the most significant results is shown by the gold bearing Quartz diorite porphyry, a distinctive well altered, narrow dyke, observed in DDH-80-1 and 2. This dyke shows that a portion of the gold in the Crescent hydrothermal system was introduced relatively late in the intrusive history of the complex.

A program of at least 4000 feet (1200 meters) of diamond drilling is recommended for 1981 as outlined in Appendix II, to run in conjunction with additional geological mapping and prospecting. This program would cost in the neighborhood of \$200,000.00.

Property work recommendations for Lockeport, Swan, Alder Group and White Bear are outlined in Appendix V. These programs would total approximately \$100,000.00.

The October South Moresby Resource Planning Team meeting was attended on October 21, 1980. A note stressing the importance of the co-ordination of input by the various parties engaged in Mineral Exploration with the B.C. and Yukon Chamber of Mines is contained in Appendix IV.

In October J.M.T. Services conducted work on their LOCK claims which completely surround the LOCKEPORT Group. Extremely recessive, arsenopyrite rich zones in Kunga Formation thin bedded black limestone carrying significant gold have been reported just north of the old townsite of Lockeport. After completion of drilling on CRESCENT Claims the drill was moved to Lyell Island for a short contract with J.M.T. on their April Group.

TIME ALLOCATION

From September 1 to October 31st time allocation to various classifications is tabulated below:

TABLE 1

TIME ALLOCATION SEPTEMBER - OCTOBER

Item Man Days Prospecting 14 Geology _ Geochemistry (all day) -**Office** 21 Drafting 19 Camp Construction and Moves 18 Travel 18 Staking 2 Core Logging 28 Core Splitting 18 2 Drill site preparation and help 2 Warehouse 150 Man Days

Individual time sheets are contained in Appendix I. Travel time is high due to the amount of driving involved from Atlin to Prince George and the mobilization into Crescent Inlet. Scott Angus and Jean Pautler were laid off at the end of October.

EXPENDITURES

As was expected the entire budget was spent as of September 1, 1980. However what wasn't expected was the amount of over run due mainly to \$7,000.00 of helicopter time spent in July that was not counted at the August 20 Committee Meeting. Up to the end of October the program has spent approximately \$ 323,732.76 which is divided between CRESCENT Claims \$180,977.78 and B.C. Gold General \$142,754.98.

Table II shows the expenditures incurred during September 1980 on the Atlin reconnaissance. Drill costs are contained in the Third Quarter Report.

Approximately \$800.00 was spent at Gnat Pass examining a group of crown grants.

Outstanding expenses for filing of assessment work and Notices to Group are

Group	<u>Due date</u>	Work applied	Filing Fees
SWAN GROUP	June 28, 1981	2 years	\$ 285.00

CAMPS AND AREAS PROSPECTED

(A) CRESCENT CLAIMS (103B12W, 13W)

(1) DIAMOND DRILL PROGRAM

A total of 761 meters was drilled in 6 holes using BQ core and a Hydrawink diamond drill from Drilcor Industries. Generally the drilling progressed with no major problems from start up on September 29 to finish on October 18. Some problem arose with inexperienced drillers near the end of the job. Drill sites and camp were prepared between September 22 and September 28 by J. Shearer, Scott Angus and one Drilcor employee.

Helicopter services were supplied by Queen Charlotte Helicopters mainly in the expectation that the Hughes 500D would be able to lift considerably more than the Bell 206B. However this was not the case and the drill skids and mast had to be stripped for each move. One day was lost due to the unavailability of helicopter support for a move. Except for the first few days setting up camp, the weather was very wet although high winds were only experienced occasionally.

Tents and frames have been stored at the Queen Charlotte Helicopter hangar in Sandspit. Some heaters and other miscellaneous equipment was left in the frame tent at the tidewater campsite.

Drill logs and assay values are shown in Appendix II and results are also plotted on cross sections illustrated on Figures 2,3,4 and 5. Locations of the holes in relation to surface geology is shown on Figure 1 (in pocket).

A variety of rock types contain anomalous gold. Table 3 gives the average and range of gold values for each lithology in the first 5 holes.

.

.

-

None of the many anomalous gold zones even approach potential ore grade material. However there are several geochemically anomalous zones over 10's of meters in the first 4 holes. The silicified gabbro in DDH-80-5 averages about 100 ppb gold over most of its first 100 meters.

Perhaps the most significant result is the relatively high gold content of the 0.76 meter wide Quartz Diorite Porphyry dyke that occurs in DDH-80-1 and 2. The pertinent data regarding this dyke are outlined below.

<u>Hole</u>	Interval <u>Meters</u>	Width Meters	Attitude	Assay ppb Gold	Core Recovery	Description from Log
DDH-80-1	5.1-5.7	0.6 m	50° to core axis	1650	75%	probable dyke white, 2 mm quartz phenocrysts
DDH-80-2	19.20 to 19.96	0.76 m	30° to core axis	4650	100%	very white, spotted with green pyroxene? Large quartz, irregular ovoid quartz eyes.

This dyke was not seen on surface. It is a distinctive rock and one of the few quartz bearing intrusives recognized on the property.

There is a definite possibility that what was seen in the two drill holes is not one dyke but two separate dykes. If it was the same dyke it would have to decrease 0.16 meters in width over 18 meters in strike and have a dip of 26° to the west. The occurrance in DDH-80-2 was remarkable for its light green pyroxene (?) crystals. A thin section is in the process of being cut on a specimen from DDH-80-1 and this may clarify some of the petrographic distinctions.

The large geochemically anomalous sections are as follows:

<u>Hole</u>	Interval Meters	Length <u>Meters</u>	Lithology	Value <u>Approximate</u>
DDH-80-1	5m-18	13	dacitic Lapilli tuff variolitic dacite	< 300
DDH-80-1	28-33	5	Rhyolite	>500
DDH-80-1	44-50	6	Chloritic Rhyolite Melanogabbro-Quartz breccia	one>5,000
DDH-80-2	7-13	6	dacitic Lapilli tuff	< 300
DDH-80-2	18-20	2	Quartz porphyry and tuff	3,000
DDH-80-2	41-60	19	dacitic Lapilli tuff and feldspar porphyry Rhyolite	>500
DDH-80-2	108-120	12	Rhyolite Breccia	>500
DDH-80-3	26-36	10	Feldspar porphyry Leucogabbro and diabase	>500
DDH-80-4	60-62	2	Rhyolite	300
DDH-80-4	82-88	6	Rhyolite	300
DDH-80-5	1-11	10	Melanogabbro	<300
DDH-80-5	32-34	2	Melanogabbro	2,500

Samples running >5,000 ppb gold or close are listed below.

5-6min	DDH-801	Quartz diorite Porphyry and dacitic tuff	1650	ppb
29-30 m in	DDH-80-1	Rhyolite, 2 cm calcite vein	>5000	ppb
49.1-49.3 in	DDH-80-1	Quartz breccia in melanogabbro	>5000	ppb
19-20 m in	DDH-80-2	Quartz diorite porphyry	4650	ppb
58-60 m in	DDH-80-2	Rhyolite, Rhyolite Bx, Chl Rhyolite	>5000	ppb
29-30 m in	DDH-80-3	Dacite, Fp porph, qts vein 0.4 cm wide	2200	ppb
70-72 m in	DDH-80-4	Leucogabbro porphyry-Fp porphyry quartz vein 3 cm wide	> 5000	ppb
32-34 m in	DDH-80-5	Melanogabbro	2500	ppb
35.66-35.95 in	DDH-80-6	Quartz vein	4700	ppb

This gives 9 assay intervals with high values with four probably due to quartz stringers and breccias, two due to Quartz diorite porphyry, two due to Rhyolite and one unexplained interval in melanogabbro.

It must be remembered that the drill logs were produced without any assay results. It may be possible to gain a better appreciation of the relationship between lithology and/or quartz veining and gold content by re-examining the core by paying particular attention to anomalous sections. This could be done in one day on the property and could be left until after the thin sections are studied.

A proposal of about 4,000 feet (1200 m) of diamond drilling for 1981 is outlined in Appendix III. This involves deepening DDH-80-2 and 4 to reach the area of highly anomalous soils and rock chip samples taken on surface at 580N + 125W. A deep hole is recommended in the same area to check for additional quartz porphyry bodies at depth. Two sets of holes (4 holes total) in the vicinity of 400N and 300N would test the southern extension of the gold soil anomaly and north part of anomalous IP effect. One hole is positioned at about 100N to further check the IP anomaly and high soils on the west side of the baseline.

Clearly, from the highly anomalous gold content of soils and rocks coupled with a prominent magnetic anomaly, the area between 50S to about 800N on the 00 baseline represents a unique system. What exactly is unusual about this area in terms of lithology, mineralization or alteration has not been isolated by work to date.

To the north along the baseline and to some extent even north of the CRESCENT Claim boundary (2 Km north of the drill sites) similar geological conditions exist with acid volcanic mega blocks engulfed in basic coarse to fine grained intrusives. Sulphide content appears to vary widely. Intense influx of silica as demonstrated by DDH-80-5 is actually north of the main gold soil geochemistry.

- 11 -

From general geological considerations coupled with the fact that a significant portion of the gold content encountered in work to date is in late stage in quartz rich intrusives or narrow quartz veins, the main potential of the property lies in the identification of areas of late stage quartz rich intrusions. One such area was observed in geological mapping on Line 1000N 200E. However no soil anomaly is coincident with this stock. This is assuming that the 1981 proposed drilling does not find gold values with the source of the IP effects or intersect quartz porphyry intrusives at depth from the crest of the hill.

Once timber harvesting has proceeded, scheduled to begin around 1984-1985, new exposures should be examined for late stage quartz rich intrusives.

S.A. Averills additional remarks (Appendix VIII) noting that much of the gold is associated with a zoisite concentrate may be related to the gold bearing quartz porphyry dykes. Thin section examination will indicate the extent of zoisite alteration.

Gear stored in Sandspit and Crescent Inlet is listed in Appendix VII.

(B) EASY INLET (92L/3W)

(1) <u>Results</u>

An assessment report has been filed with the Department of Mines. All results are discussed in that report and shown on Figures 7 and 8. (in pocket)

Soil samples and rock geochemistry gave negative results with no zones of follow up indicated. No further work is proposed.

Geological mapping established the presence of a relatively complex volcanic stratigraphy characterized by intermediate to felsic flows and pyroclastics. At least some of the dacitic units are in the form of high level intrusions.

To adequately understand the relationship between the dacitic intrusions and the epizonal monzonite pluton to the north and the alteration zones on the small peninsula to the east a systematic program of geological mapping is required. A suite of thin section will be needed to identify some of the more subtle variations within the predominately fine crystalline volcanic facies.

The present work indicates that surface sampling is not helpful in defining areas of concentrated interest. A comprehensive geological map is warranted on perhaps a scale of 1:2900. The mapped area should include the Kashutl pluton.

- 14 -

(2) Ououkinish Mainline - BP Area

Limited prospecting was directed toward the small epizonal pluton in the Ououkinish Valley near Km 13 on the Ououkinish Mainline and around a quartz porphyry stock - silicified limestone contact near Km 11.5, (referred to as the BP area). Several of these quartz porphyry intrusions are reported around the Kashutl pluton and Falconbridge in 1971 did some soil sampling for copper-zinc in the BP area. Results are shown on Figure 9 for all samples and on Figure 10 in more detail in the BP area. Two rocks and two soils are anomalous for gold ranging up to 340 ppb gold. The BP area should be followed up with more soil sampling and geological mapping.

(C) BROOKS PENINSULA (92L/4W)

 \tilde{v}_{ϕ}

Two short camps were established at Brooks Peninsula, initially near the mouth of Amos Creek and the second near the headwaters of "Gold Creek". Colours were noted in lower Amos Creek. Vegetation on Brooks Peninsula is very dense salal underbrush among stunted windblown cedars.

Brooks Peninsula is underlain by a katazonal assemblage of gneiss, amphibolite, agmatitic quartz diorite and migmatite. Well exposed mylonite forms most of the beach along the west side.

Results of sampling are shown on Figure 11. No anomalous values are apparent and no sulfide zones of any appreciable extent were seen in the field.

KENNEDY LAKE (92F/4E)

A Tertiary gabbro stock situated on the west shore of Kennedy Lake was rapidly examined and sampled. Location and results of sampling are illustrated on Figure 12. All soils and rocks are uniformly low. The gabbro turned out to be a melanocratic, medium crystalline intrusive with abundant large clots and patches of pyrrhotite with minor pyrite. Occasionally pronounced pyrite zones were seen. These areas were intensely altered zones of silicified hornfels that appeared to be altered Quatsino Formation limestone. This altered limestone has the same texture as the rhyolite fragments at CRESCENT on Gabbro Hill.

Several old gold showings are known north and east of Kennedy Lake. Large masses of Tertiary quartz diorite, similar to the stock at Zeballos, occur around the south and east side of the lake. Placer gold is reported form the mouth of Old Shoe Creek.

In summary, although the present program on one specific target did not uncover any interesting zones the Kennedy Lake area in general warrants detail follow up work.

(E) <u>KING ISLAND (93D/4E,W</u>)

KING 1 to 6, two post claims were staked on southern King Island near Bella Bella - Ocean Falls as shown on Figure 13.

The claims are underlain by a rhyolitic assemblage of flow banded rhyolite and rhyolite breccia grading down through feldspar porphyry to a subvolcanic miarolitic alkali intrusive - (monzonite syenite). Rusty rhyolite was noted along a prominent east-west gully near the southern end of the claim block.

The subaerial facies extends considerably to the northeast but time did not permit an examination of this area. A molybdenite prospect is being drilled by BP Minerals to the south in a similar setting.

Results of available sampling is shown on Figure 14. No anomalous values were obtained. The general area to the north-east and lower elevations to the east should be prospected in a reconnaissance fashion before the claims are allowed to lapse.

FIGURE 14

(F) GOLDEN EAGLE (82E/1W)

A summary report has been written and two copies sent to the owner J. Stoochnow. Some minor changes were made in the geological legend to more accurately reflect the stratigraphy of the area.

Preliminary results of the limited sampling undertaken in 1979 on this property indicate three gold soil anomalies that should be checked by detail sampling and backhoe trenching if necessary.

Ownership of all key claims should be consolidated under one working agreement to facilitate the orderly exploration of this interesting area. A concerted effort to find all sources of data on previous work, especially diamond drilling should be a priority.

(G) TULSEQUAH - ATLIN AREA (104K, 104N)

(1) Introduction

A short reconnaissance prospecting program was conducted in the general Tulsequah - Atlin Area by J. Shearer and Scott Angus between September 5 to 17. Five days were spent travelling with one day lost due to snow at Whitehorse airport and the necessity of bussing from Watson Lake. This left 8 field days. Transportation was by Bow Mac pick-up already in Whitehorse for the D.C. Syndicate and this was returned to Prince George.

All normally expected facilities are available in Atlin including: Mining Recorder - Gold Commissioner, 2 stores, gas and Bulk Dealer, 1 motel, 1 hotel, cafe and lounge, Helicopter base, Red Cross hospital, local contractors in welding, road construction and etc., several fixed-wing airlines, trucking and cartage services, bus schedules, laundromat and a Mineral Exploration expediting service.

Some work was also done out of Dease Lake in the Heart Peaks region which is slightly closer to Dease Lake than Atlin. Telegraph Creek is also about the same distance to this area.

Weather conditions were generally good with no down time due to poor weather. Fresh snow was common above about 5200 feet but this did not hamper any work at the sites examined.

A total of 64 soil, 5 silt and 26 rock samples were collected and run for gold, silver, arsenic, antimony and mercury. Results indicate a large silver anomaly in the Heart Peaks area of up to 12 ppm silver in soil. Some weakly anomalous values were found at McGavin Creek Caldera in Ag, As, Hg, and Sb. One relatively high gold in rock (660 ppb Au) was encountered at Kennicott Lake.

- 26 -

An outline of prospecting done is listed below:

September 7 visit Adanac, examine Atlin Placer District.

- September 8 McGavin Creek Caldera
- September 9 O'Donnel River section
- September 10 Pillman Creek, Mount O'Keefe
- September 11 Simpson Creek Stock, Pillman Creek
- September 12 Staking Pillman Creek
- September 13 Travel to Dease Lake
- September 14 Kennicott Lake
- September 15 Heart Peaks reconnaissance

Initially fly camping was anticipated, especially in the McGavin Creek Caldera and Pillman Creek, however the availability of helicopter support did not allow camps to be established.

(2) REGIONAL GEOLOGY - (Tulsequah - Atlin Area)

Geology of the Tulsequah-Atlin Area has been compiled by Aitken (1959) and Souther (1971) on the scale of 1:250,000, refer to Figure 15 (in pocket). A more generalized version of these maps has been constructed by Souther and others (1978) as Map 1418A (Iskut River) in thel:1,000,000 Geological Atlas series. Early work in the Atlin and Tulsequah regions has been dealt with by Mandy (1930), Kerr (1948) and Cairnes (1913).

The general geological parameters discussed in this section also apply to surrounding areas such as Dease Lake, Teslin, McDame and Whitehorse map sheets which are covered in reports by Gabrielse (1963) Wheeler (1961) and Mulligan (1963). A recent compilation of Tertiary rocks and structures has been made by Noel (1978). These studies and others are contained in the list of references at the back of the report.

Regionally going from west to east the Tulsequah-Atlin Area is composed of the eastern flank of the Coast Plutonic complex: the Intermontane Belt and finally the Omineca Crystalline Belt. The Intermontane Belt can be subdivided into the Atlin Terrane (Monger 1975) and a zone between the Coast Plutonic Complex and the Atlin Terrane boundary, the Nahlin Thrust Fault, and north of the Stikine Arch. In older publications this zone is usually referred to as the Whitehorse Trough or Belt.

In 1980, prospecting was confined to the Whitehorse Belt between south-eastern Atlin Lake and Stikine River. Although several attractive exploration targets exist in the Atlin Terrane it will not be discussed since no 1980 work was done north of the Nahlin Fault aside from a brief reconnaissance of the Atlin Placer District. The Whitehorse Belt is characterized by a complex structural and depositional history that can be essentially summarized as follows:

- (1) deposition and metamorphism of Paleozic Assemblages
- (2) development of Stikine Arch
- (3) extrusion of thick Mesozoic Volcanics and intercalated sediments mainly in the Triassic (Stuhini Group)
- (4) Upper Carbonate Facies (Sinwa Formation)
- (5) deposition of the mainly coarse clastic Laberge Group, Takwahoni Formation and Inklin Formation)
- (6) Uplift and Intrusion of Jurassic to Cretaceous plutons, some associated with the Coast Plutonic Complex
- (7) Major thrust faulting, over thrusting of the Atlin Terrane development of the King Salmon Thrust
- (8) Early Tertiary acid to intermediate explosive Vulcanism and associated high level intrusions (Sloko and Skukum Groups)
- (9) Block faulting and erosion

note: 5, 6 and 7 are interrelated and affect each other.

Prospecting in 1980, due to lack of time, focused only on the last major deposition event, that of explosive Tertiary vulcanism. If additional time was available parts of the older sequences which surround the Tertiary volcanics would have also been examined. Early to late Tertiary acid to intermediate volcanic rocks in the Whitehorse Belt and eastern flank of the Coast Plutonic complex are preserved in synvolcanic graben, half graben and cauldron subsidence structures, associated with high level pluton emplacement and ring dykes. One of the best documented cauldron subsidence structures is near Bennett Lake (Lambert 1974). Souther (1971) describes the Sloko Group as follows Page 29:

> "The Sloko Group comprises a bright coloured assemblage of intermediate to acid volcanics and derived sediments that rest with profound unconformity on Jurassic and older rocks. The great majority are pyroclastic, varying from coarse explosion breccias and agglomerates to fine-grained, delicately banded vitric tuffs and ignimbtites.
(b) HEART PEAKS

One day, September 15, was spent checking the Heart Peaks Formation and briefly the Samotua graben. Heart Peaks are in the Dease Lake map sheet but the Heart Peaks Formation is almost wholly within the eastern edge of the Tulsequah map area. Souther (1971) gives the following description.

> "The brightly coloured group of pyramid-shaped summits on the western flank of Heart Peaks forms a prominent landmark, visible for many miles. The area is underlain by rhyolitic and Trachytic lavas, tuffs and breccias that weather to bright hues of red, yellow, and orange. The fresh lavas have a light grey to purplish grey aphanitic matrix surrounding clear light grey, tabular phenocrysts of feldspar, occasional books of biotite, and small rounded blebs of quartz. Quartz stringers and quartz-lined vugs are locally abundant."

Figure 21 shows the location and results of soil and rock sampling done in the Heart Peaks Formation. Soils are anomalous in silver up to 11.0 ppm Ag. Rock samples are geochemically anomalous in silver with up to 12.0 ppm Ag in silicified rhyolite and amethyst bearing quartz veins. Also slightly anomalous values are apparent in gold, up to 60 ppb, arsenic mercury and antimony. If additional prospecting in 1981 is approved by the Syndicate Committee a block of 120 units is proposed to cover the area most likely to contain anomalous silver values and a small program estimated to cost \$30,000.00 should be carried out. The claims would be mainly above treeline and necessarily entirely helicopter supported from Atlin or Dease Lake. At least 2 campsites would be needed.

- 30 -

Faulting and volcanism were at least partly contemporaneous. At many localities pyroclastic rocks grade imperceptibly downward into uniform felsite which further grades into fine grained monzonite. This feature was also noted on the King Claims on King Island near Bella Bella about 600 miles to the south. The Sloko Group has many similarities to the Masset Formation, especially the southern facies of the Queen Charlotte Islands.

Prospecting targets for bulk tonnage mineralization in the Tulsequah-Atlin area are envisaged along the lines of the diverse ore deposits reported in the San Juan Mountains in Colorado and elsewhere (refer to reference list especially Lipman and others 1976, Steven 1968, 1965, Swanson and others 1978; etc.) An emphasis on bulk tonnage type settings has been maintained throughout.

These types of rocks are also present in the Ootsa Lake area and as far north as the Klotassin River in south-western Yukon Territory.

(3) 1980 PROGRAM

(a) PILLMAN CLAIMS

On September 12 a fifteen unit claim PILLMAN ONE was located to cover a small gabbro stock shown by Aitkin to be exposed in Nower Pillman Creek. The western boundary of the claims are about 5000 feet (1500 meters) from Atlin Lake as shown on Figure 16. A good foot path has been made from Atlin Lake to a recently built cabin in the center of the claim block. Numerous helicopter landing spots are available throughout the area and along the creek valley. The forest is mainly open White Pine with a few sections of dense alder and buck brush around swamps. The area is characterized by a series of small low hills a few hundred feet at most in elevation that gradually slope down toward Atlin Lake with many interconnecting ravines and gullies.

During the early part of the century until the 1920's, Mr. Pillman the town mortician with several associates (all the small tributaries of Pillman Creek have names) had placer leases on Pillman Creek from which only very fine placer gold was recovered. Currently a local Atlin resident who has a reputation of being a "back-to-the-lander" and Eco-freak has a placer lease (PML 1774) and has built a very substantial cabin which was finished in 1980. A sluice box and other placer equipment were noted on the creek upstream from the cabin.

The PILLMAN ONE Claim and also PML 1774 are well within Atlin Park. PILLMAN ONE was accepted for recording on September 19,1980 and has been duly recorded in Atlin and assigned a record number. According to the Gold Commissioner for the Atlin Mining Division in Atlin, who was consulted prior to locating the claim, it is permissable to stake claims in Atlin Park. The Gold Commissioner of the Vancouver Mining Division, David Doyle, could not find any record of Atlin Park although he did have information on the Atlin Recreation Area. A policy of different classes of parks is still in effect, ranging from A to C according to Mr. Doyle.

An unsettling aspect of working in Parks is that the Chief Gold Commissioner, R. Rutherford has stated that there is no staking of any sort in B.C. parks. Also R.A. Reyes, a claims inspector in the Vancouver Office, has said that the different classes of parks have been abolished and there is no longer any staking in parks.

The Gold Commissioner in Atlin and the local Fish and Wildlife officer in Atlin did not know the class of Atlin Park. Presumably to find out anything about Atlin Park a Mr. Green at the Skeena Regional Office of the Lands, Parks and Housing Ministry, Smithers, B.C. Box 970, VOJ 2NO, telephone 847-4411 should be contacted.

In summary, the PILLMAN ONE has been recorded in the usual manner indicating the Atlin Park is a Class C Park. Preliminary exploration can proceed in the normal manner. There is however some question as to the meaning of seemingly contradictory statements from employees of the Department of Mines. It is also surprising that more easily obtainable information is not available on Atlin Park which was apparently created around 1974 or 1975.

The geological contacts plotted by Aitken (1959) are shown on Figure 17. Much of the area shown by Aitkin as underlain by the gabbro stock is actually good exposures of coarse clastics of the Laberge Group in the creek canyon. Some intrusive was noted at the west and east extremities as shown by Aitken. However a large expanse of gabbro was observed along the north claim boundary.

A large hill between 3N 2W and 3N 3W is composed entirely of several phases of coarse to fine crystalline gabbro. Mafic rich sections are common. Many rusty inclusions were seen near 3N 3W. It is clear that Aitken has made a mistake on his 1:250,000 mapping and that the gabbro stock is much more complicated than shown and apparently is mainly to the north. The limited soil samples taken are not anomalous

FIGURE 17

but they are mainly located in the south underlain by Laberge Group.

In summary the PILLMAN ONE Claim is located on a structural and lithological setting very analogous to Crescent Inlet. Only the briefest reconnaissance was possible in 1980. The claims are easily accessible and warrant preliminary soil geochemistry, rock sampling and prospecting. The area to the east toward Mount McCallum should also be covered.

(c) OTHER AREAS PROSPECTED IN 1980

Only one day was spent on the McGavin Creek Caldera, so just the east end was examined. The location and limited sample results are shown on Figure 19. Souther (1967) describes the McGavin stock, on page 170, as follows:

> "...a roughly circular body of granophyric leucogranite approximately two miles in diameter that cuts unmetamorphosed lower Jura ic greywacke and shale. The stock is surrounded on three sides by pyroclastic breccia composed of banded vitric rhyolite fragments and accidental fragments of Lower Jurassic sediment in a matrix of crushed rocks and impalpable glass. The breccia appears to be cut by the leucogranite and is considered to be an early effusive stage of the same magma that formed the stock. The breccia is separated from the Jurassic sediments by a series of faults which are roughly circular in plan and dip steeply inward toward the stock. The breccia has been dropped down at least 300 feet relative to the enclosing Jurassic sediments suggesting a cauldron subsidence related to emplacement of the leucocratic stock."

Results indicate slightly anomalous concentrations of silver, arsenic, mercury and antimony. One rock sample contained what appeared to be tetrahedrite and galena, however it only ran 10 ppm silver. This was an extremely pyritized and silicified rhyodacite. Purple fluorite was noted in several spots. Under the binocular microscope sphalerite was noted in the rhyodacite.

In summary, only a very small part of the McGavin Creek Caldera was examined. A comprehensive program is recommended.

Figure 19

Half a day was spent on each of the following areas; Mount O'Keefe, Simpson Creek Stock and Kennicott Lake. Location and results of samples taken on Mount O'Keefe are shown on Figure 20. Three small plugs of what Aitken (1959) calls granophyre occur in the area shown by Figure 20. These are white weathering light coloured rocks composed of quartz eyes in a very fine crystalline matrix. They are in the form of dykes about 20 m wide trending 095°. The Mount O'Keefe area has been the site of repeated exploration with many sets of claim posts and cairns observed. At one point a cat road was built and considerable trenching done. However the source of high grade copper float has not been found.

Samples collected on the dioritic stock near Simpson Creek, Figure 21, show very low values for all elements except mercury in soils with up to 400 ppb Hg. More prospecting to the west is warranted in this area of thick glacial cover. The Nahlin Fault is shown by Aitken as truncating the Sloko volcanics associated with the Simpson Creek Stock. A large Sloko age diorite stock composing the core of Paradise Peak was not examined due to the high elevation and new snow conditions. Paradise Peak stock is unique in that it is partly outside Atlin Park.

A gold occurrence near Kennicott Lake approximately 50 Km north-west of Telegraph Creek Townsite was investigated. Since the discovery of this gold occurrence in the early 1960's there has been several large cat trenching programs done in the general vicinity on porphyry copper type mineralization. The original gold showing was found and a quartzcalcite vein specimen ran 660 ppb Au. No further work appears warranted since the gold showing is a minor vein type and is peripheral to a large porphyry copper system. Much of the porphyry system is presently held by Hudson Bay. The area could be examined again if and when these adjacent claims are dropped in light of the high gold content of the prophyry system currently being evaluated by Consolidated Silver Ridge near Mount Edziza about 50 miles to the south.

(H) 1981 PROGRAM RECOMMENDATIONS

Appendix VI contains proposed budgets for the 1981 season for properties other than Crescent Inlet.

The ones considered most important are:

(1)	SWAN Claims	\$ 29,000.00
(2)	ALDER GROUP	34,000.00
(3)	LOCKEPORT Claims	25,000.00
(4)	WHITE BEAR	17,000.00
	Total	\$105,000.00

It must be realized that each of these estimates is independent of each other and the Crescent Program so that if mobilization costs were reduced the estimates would be much lower.

Depending on the decision of the Syndicate Committee regarding further prospecting, an estimate of \$32,000.00 will be required to follow up the Heart Peaks anomaly.

General program proposals are contained in each estimate for the individual properties.

CONCLUSIONS AND RECOMMENDATIONS

Diamond drilling on CRESCENT Claims indicated that potentially ore grade mineralization does not underlie the main gold anomaly in the vicinity of 500N at shallow depths. Weakly anomalous gold is contained in a variety of rock types with perhaps the most significant new information shown by the relatively high gold values in quartz diorite porphyry dykes. Future exploration should focus on these late stage quartz rich intrusions. Drilling in 1981 is recommended on the remaining portions of the gold soil anomaly and should total about 4000 feet (1200 meters) which would cost, in the neighborhood of \$200,000.00.

A program of property work is outlined on the SWAN, ALDER, LOCKEPORT and WHITE BEAR Groups estimated to cost \$105,000.00 in 1981.

Follow up prospecting is warranted in the BP-Ououkinish Mainline Area, King Claims and Heart Peaks anomaly. A policy decision on the direction of the Syndicate in 1981 regarding additional grass roots prospecting is needed. The third and final year of grass roots prospecting of the present program officially ends in 1980.

A Syndicate Committee Meeting is scheduled for December 8, 1980.

Respectfully submitted,

J.T. Shearer

Inter Office Correspondence

Subject: South Moresby Resource Planning Team

Shearen

STEPHEN EXPLORATIONS LTD. 1458 Rupert Street, North Vancouver, B.C. V7J 1G1

Telephone (604) 988-1545

November 5, 1980

INTEROFFICE CORRESPONDENCE

ATTENTION: J.C. STEPHEN

FROM: J.T. SHEARER

RE: SOUTH MORESBY RESOURCE PLANNING OCTOBER 1980 TEAM (SMRPT) MEETING

On October 21, 1980 I attended the monthly meeting of the South Moresby Resource Planning Team (SMRPT) which was held at the Legion basement in Queen Charlotte City. Colin Harivel also attended in the capacity of observer for the B.C. and Yukon Chamber of M nes although he had to leave before the meeting was adjourned. The following notes are what took place in Colin's absence.

A most significant development was the decision to publish an INTERIM REPORT to be distributed early in 1981, perhaps even by February. It is extremely important that the Chamber participate in this interim report by coordinateng a concensus veiwpoint from all interested parties engaged in Mineral Exploration throughout the South Moresby "Wilderness" area. Individuals and companies that should be contacted are:

- (1)JMT Services who will perhaps represent Chevron, Placer and Superior Oil.
- (2)UMEX
- (3) Roy Woolverton
- (4) Falconbridge (Jedway area)
- Teck (Burnaby Iron) (5)

and others from a check of up to date claim maps. Texasgulf. (6)

The interim report will take the general format of :-

(a) Introduction

(b)

- (1)Individual Statements Forestry
 - (2)Fish & Wildlife

(3) Ecological Reserves

- (4) Parks Canada
- (5) B.C. Parks
- (6) Federal Fisheries
- (7) Island Protection Society
- (8) Skidegate Band Council
- (9) Queen Charlotte Museum
- (10) B.C. Ministry of Mines
- (11) Rayonier Canada
- (12) Public Representative
- (13) B.C. & Yukon Chamber of Mines ???
- (c) Option Choices, 4 or 5 options (from the current 7)
- (d) Implications (cost/benefit, management considerations, time factors)
- (e) Conclusions

Optimistically the chairman is proposing a total of 30 pages. A public meeting would be scheduled after the Interim Report is published (mimeographed) perhaps for March 30, 1981. It was generally agreed in private that if an Interim Report is prepared, the likelyhood of a political decision based on it is very strong, and a final report will never be completed.

The individual statements will consist of the unedited position of each participant in the Planning Team (although it was not absolutely clear if the Chamber will be asked to contribute) boiled down to 1 or 2 pages. This is where the Chamber should demand to have a voice. Several meetings will have to be organized by the Chamber in Vancouver to bring together all the ideas from the various claim holders in the SMWP area to be ready to submit a unified statement for the January 1981 South Moresby Resource Planning Team meeting.

Next meeting was tentatively set up for November 25 with no meeting in December. The Windy Bay question will be extensively discussed at the November meeting.

Budget Proposal 1981

SWAN Claims ALDER Group LOCKEPORT Claims WHITE BEAR

Miscellaneous:

SINGA Claims KING Claims Heart Peaks McGavin Creek Caldera

B.C. GOLD SYNDICATE

Work Proposals - J. Shearer recommendations 1981

(1) SWAN CLAIMS (a) comprehensive geology map, detail prospecting, rock geochem. 4-5 man crew, 3-4 weeks. (2) ALDER GROUP trenching on east Alder Island, completion of (a) reconnaissance geology on Burnaby and Huxley, some prospecting, rock geochem. 4 men, 3-4 weeks. DRILLING ON ALDER VISIBLE GOLD SHOWING. (3) LOCKEPORT CLAIMS (a) detail geology, detail prospecting, rock geochem 2-3 weeks, camp on top 2-3 men (4) SINGA CLAIMS (a) general prospecting 2 men 1 week or less, mobilize out of Wilson Bay. (5) TAR - No Work, wait for completion of road work, then limited trenching and exam. of road cuts. (6) Hawks Nest - No Work (7) Lyel1 - No Work (8) EASY CLAIMS- No Work (9) KING CLAIMS general prospecting (a) 2 men 1 week, mobilize from Port Hardy or Bella Coola EASY Recce on Ououkinish Mainline Km 13, BP area 2 men 1 to 3 days follow up (10)(11)DEADWOOD ONE - No Work (12)WHITE BEAR (a) trenching, plus detail geology 2 men, 2 weeks (13) PILLMAN NO WORK IF PARK POLICY IN EFFECT NO ANOMALIES (14) HEART PEAKS stake claims, detail geology, prospecting, soil and rock geochem. 3-4 men, 3 weeks

(15) McGavin Creek Caldera - stake claims, detail prospecting, soil, rock, geology. no anomalies. 10 ppm Ag in one rock

OVERBURDEN DRILLING MANAGEMENT LIMITED 192 Powell Avenue, Ottawa, K1S 2A5 29 VANSON AVENUE, DITAWA, DITARIO K2E 6A9 - (613) 822-0202

September 23, 1980

Mr. J. C. Stephen J. C. Stephen Explorations Limited 1124 West 15th Street North Vancouver, B. C.

Dear Mr. Stephen:

Re: B. C. Gold Syndicate, Queen Charlotte soil Samples

As shown in the attached Table, we have panned the retained 1/2 split of the heavy mineral concentrate from each soil sample, and have determined the number of gold grains in the pan concentrates. Since panning cannot recover all the gold, particularly where both fine and coarse grains are present, the indicated counts are a minimum. The two mid-density concentrates for which high analyses were reported (Sample 01-770 ppm; Sample 04-1920 ppm) were panned also but no free gold was found.

Note that the number of grains of Au per kilogram (dry) of -10 mesh soil (excludes pebbles and cobbles) ranges from 6 to 15, which translates into a relatively constant grade of 0.003 to 0.006 ounces per ton.

The gold grains are fine (20-200 microns). The largest grains occur as delicate leaves and wires that clearly have not undergone transport. Chemically resistant quartz is still attached to some of the grains, but all other vein and rock-forming minerals have been destroyed by the severe leaching that produced the auriferous residual soil. However, the gold is confined to concentrates that contain zoisite (Samples 04-08), indicating that the source veins occur in a rock type such as andesite that produces significant concentrations of zoisite when altered.

I trust that the above meets with your immediate requirements. Should you require any additional information do not hesitate to contact the undersigned.

Yours truly,

S. A. Averill President
