News Release

October 28, 1987

Initial assay results of grab samples from the discovery trench on the Indata project have been received. Two float samples of quartz-sulphide vein material were submitted prior to the trenching and these returned the following values:

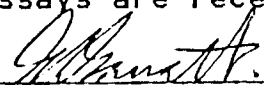

- G-I-87-4-1.26 oz./ton silver and 0.111 oz./ton gold.
- G-I-87-26-4.28 oz./ton silver and 0.066 oz./ton gold.

Within the discovery trench, seven quartz veins were exposed and grab samples of these veins were submitted for assay. The veins comprise only a portion of the zone, with the rest of the material between the veins comprising a strongly oxidized and leached earthy material that is believed to have been a high sulphide bearing, quartz deficient rock. Samples of the oxide material have also been submitted but the results for these have not yet been received. The assay results for the seven quartz-sulphide vein grab samples, which showed varying degrees of oxidation and leaching, are:

Sample No.	Silver (oz./ton)	Gold (oz./ton)
I-TR-A-1	1.48	0.102
I-TR-A-2	3.34	0.149
I-TR-A-3	2.03	0.085
I-TR-A-4	2.70	0.152
I-TR-A-5	0.52	0.051
I-TR-A-6	0.31	0.062
I-TR-A-7	2.05	0.053

avg A₁/A₀ = 1.8.9

The results of the oxide samples should be received in the next two weeks. Preliminary visual examination of the drill core indicates that the thickness of the zone is greater than the ten foot minimum thickness exposed in the trench. The drill holes have intersected the zone below the level of strong oxidation and sampling in this material should give a more reliable estimate of the grades. Further information will be released when the drilling has been completed and the core assays are received.
