

Pitquah Junction Property:

This property is an occurrence of disseminated copper sulphides in a "layered basic intrusive" near Lytton, B. C. The property is controlled by Hudson's Bay Mining and Smelting but has been largely dormant since the mid 1960's. It was originally thought that it might have the potential for developing a very large low-grade deposit. However, subsequent research revealed that there are several mineralized zones interspersed with barren country rock. The potential size is probably limited to less than 20 million tons.

Dusty Mac Property:

Examination of the Dusty Mac property confirmed its similarity to the so called "Waterloo-Type" precious metal occurrences which have thus far been known only in the United States. It appears to be the product of hot spring activity in an area of Tertiary acidic volcanism. This property is now mined out and in itself is not of interest. However, it indicates the potential for similar occurrences of this type in certain areas of British Columbia. Areas of Tertiary, acidic volcanism
