EIGHTY-EIGHT PROPERTY

The Eighty-Eight property consists of one 20 unit claim. It is located about 115 km southwest of Vanderhoof and about 10 km south of the Capoose Lake silver deposit. It covers an area of moderate to locally steep terrain varying from 4500 to 5500 feet in elevation. It is easily accessed by the Kluscius forestry access road and the Capoose Lake access road. Recent clearcut logging has exposed new areas east, southeast and northeast of the claim area.

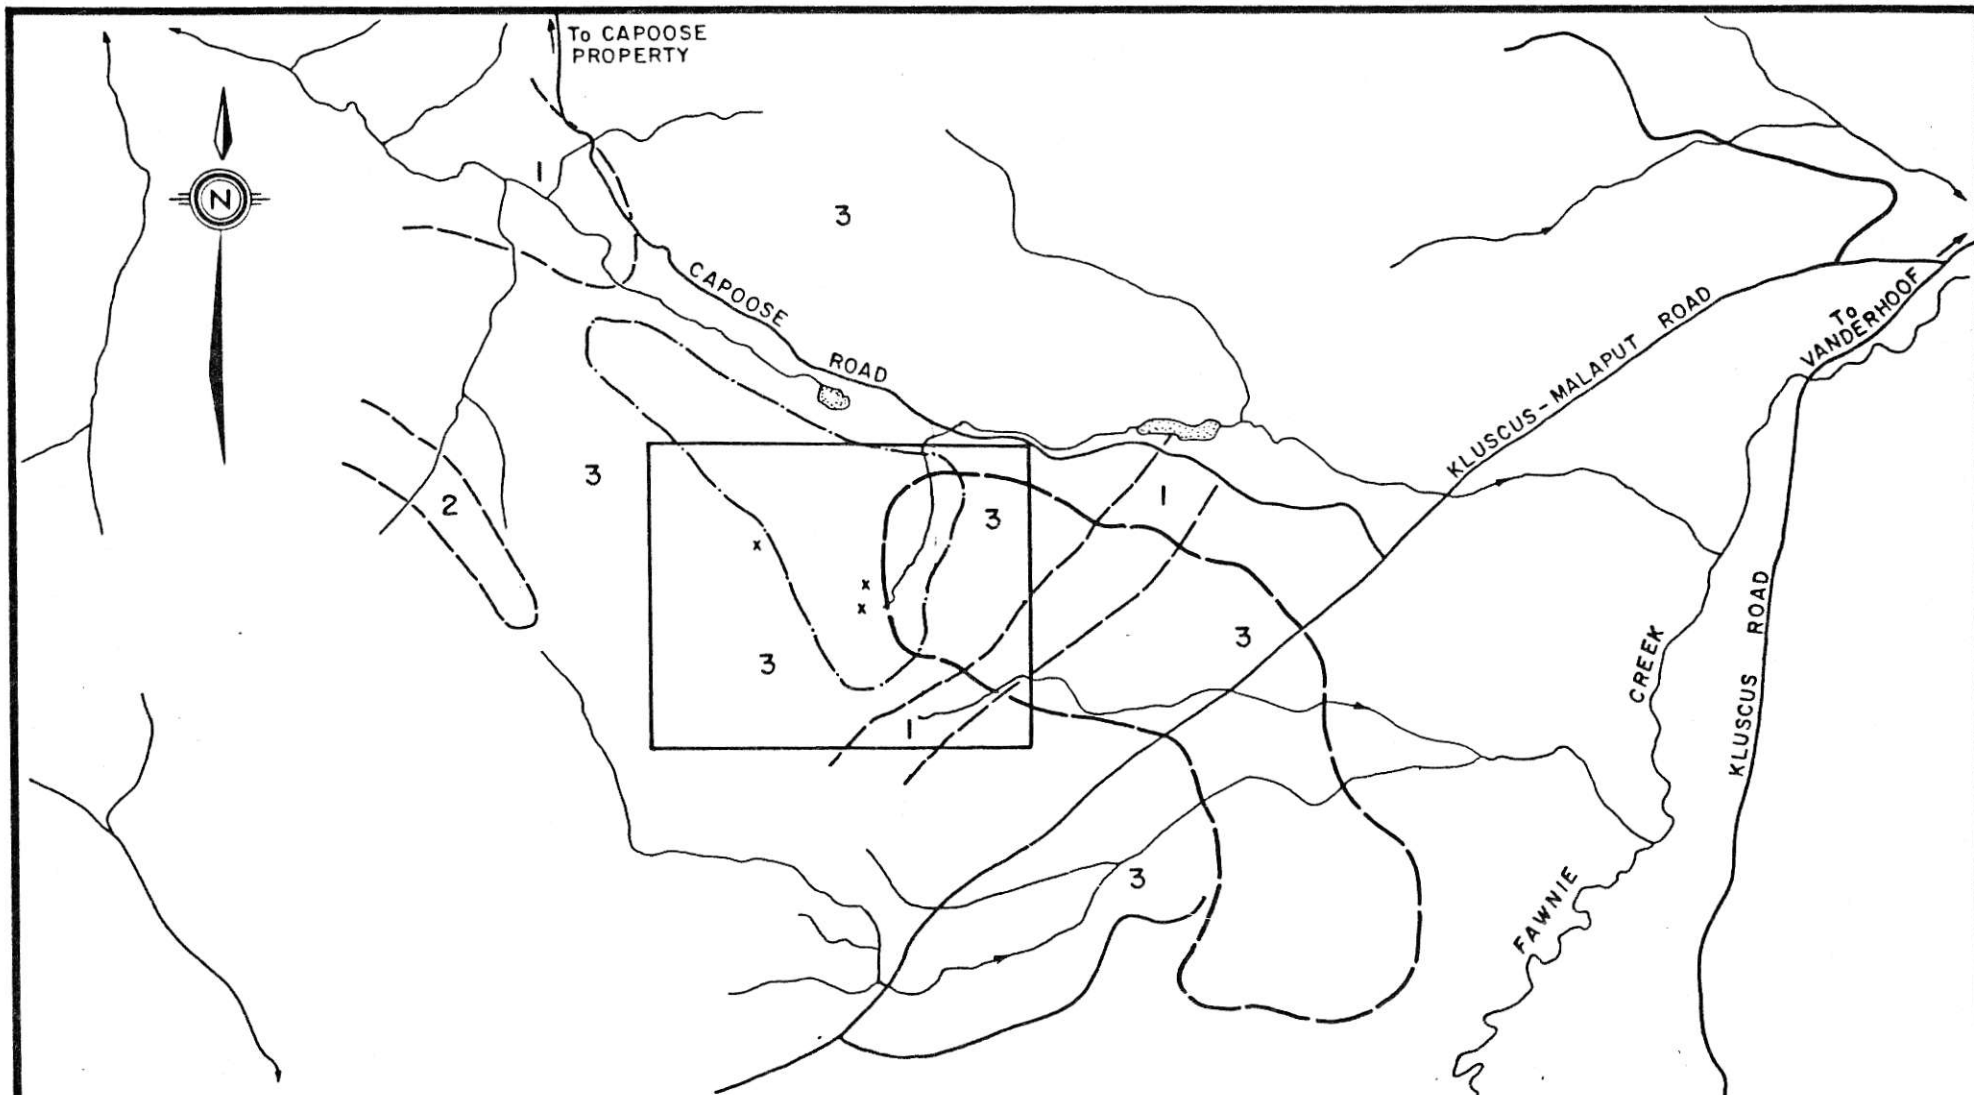

The Eighty-Eight claim was formerly covered by the Gran and Laid claims which were staked by BP Minerals Ltd. in 1981 to cover lake sediment and soil geochemical anomalies obtained during an initial survey of the area. BP's exploration target was a volcanic hosted base metal/precious metal deposit similar to the Capoose Lake or Sam Goosely deposits. During 1982 to 1984, BP carried out geochemical soil and rock sampling, geological mapping and backhoe trenching. BP allowed the claims to lapse in 1986.

The property is underlain by the Middle Jurassic Hazelton Group which is here represented by volcanic flows, tuffs and breccias of rhyolitic to andesitic composition. Most units appear to be relatively unaltered and in general hard and resistant with little pyrite or iron oxide staining evident. A coarse, rhyolitic agglomerate unit forms prominent exposures immediately east of the claim area. This unit, which is characterized by well-rounded, dark grey to black, dense rhyolite fragments up to 8 cm in size within a welded, fine grained pyroclastic matrix, appears to be of subaerial origin. Other units in the area, which include intermediate to felsic lapilli tuffs, flows, argillite and siltstone, are interpreted to have been deposited in a subaerial and/or shallow marine environment.

The main showings, which were uncovered by trenching in 1983 and 1984, are located near the crest of a steep, northerly slope near the center of the Eighty-Eight claim. These trenches were examined but unfortunately, all of them have sloughed in with very little bedrock now exposed. A few small piles of soft limonitic material remain beside one of the trenches. According to assessment reports filed by BP, the trenches exposed spotty, weak to moderate Pb/Zn/Ag/Au mineralization associated with narrow fault zones. It was felt that the main geochemical anomalies had been adequately tested and no further work was justified.

An area with a cluster of low to moderately anomalous gold-in-soil values outlined by BP east of the Eighty-Eight claim was also examined. The area of the anomalies is associated with an outwash fan which would appear to imply that the gold is of placer origin.

In view of the results of the work carried out by BP, the small size and erratic nature of the showings discovered to date, and the lack of any other obvious target areas, further work on the Eighty-Eight claim is not recommended.

EIGHTY EIGHT RESOURCES LTD.

GEOLOGY & GEOCHEMISTRY

88 CLAIM
OMINECA MINING DIVISION
BRITISH COLUMBIA

TECH WORK BY:
DAWSON GEOL. CONS. LTD.

SCALE: 1:50,000

DRAWN BY: JMD/ rwr

DATE: DECEMBER, 1989
