## 1.0 INTRODUCTION

The Ren property is comprised of two contiguous claims totalling 1009.19 ha. Jody R. Dahrouge acquired the two claims, Ren 1 and Ren 2, in November 2009 and has held them in trust for 877384 Alberta Ltd. (877384) and its co-operator Zimtu Capital Corp. (Zimtu). Dahrouge Geological Consulting Ltd. (Dahrouge) of Edmonton, Alberta, conducted a prospecting program on September 13<sup>th</sup>, 2010 at the request of 877384 and Zimtu. Fieldwork focused primarily on a preliminary geological assessment of carbonatites and related rocks on the Ren property and their potential for hosting rare earth element (REE) and rare metal mineralization, with a secondary consideration of base and precious metals. During the course of the field program, a total of 29 rock samples were collected from the Ren Property and adjacent un-staked tenures; analytical results of these will be discussed in Section 5.0.

### 1.1 GEOGRAPHIC SETTING

#### 1.1.1 Location and Access

The approximate center of the Ren Property is located roughly 55 km northwest of Revelstoke, British Columbia (Figure 1.1) just south of Ratchford Creek. Perry River-North Fork Road, which is located about 43 km west of Revelstoke along the Trans Canada Highway (TCH) and approximately one kilometre south of the Perry River Bridge, grants access to the property (Figure 1.2). Running along the west bank of the Perry River, Perry River-North Fork Road acts as a main service road for forestry operations in the area, paralleling the riverbed northward for nearly 28 km. Further northward is a crossing at Ratchford Creek whereby the claim boundaries can be reached by heading west along a series of forest service roads. From here an ATV can reach the lower parts of the claims, whereas higher elevations must be traversed on foot or accessed with helicopter support.

#### 1.1.2 Topography, Vegetation, and Climate

Located in the Monashee Mountains, property topography ranges from 600 m along the bed of Ratchford Creek to 2000 m elevation above sea level, with surrounding local topography ranging anywhere from 600 m to 2600 m elevation above sea level. Temperatures in the area

normally range from -15 °C to +25 °C, with precipitation typically averaging between 120 cm to 160 cm per year. Continuous snow cover usually extends from early November to May, with a snowpack commonly exceeding a meter in thickness. Vegetation in the region is dominated by dense coniferous forest, which includes varieties of spruce, cedar, hemlock, fir, pine and larch. Deciduous trees and shrubs such as aspen, willow, alder, and devil's club also occur throughout the area, along with a variety of fruit-bearing plants including wild raspberry and wild thimbleberry. Tree and plant populations become increasingly sparse above the standing tree line, which is at roughly 1600 m and 2000 m above sea level on steep and gentle slopes, respectively.

## 1.2 PROPERTY

Jody R. Dahrouge staked the Ren claims in 2009, and has held them in trust for 877384 Alberta Ltd. and its co-operator Zimtu Capital Corp. The Ren Property refers to two contiguous claims, Ren 1 and Ren 2, located within the Kamloops Mining Division and totalling 1009.19 ha (Figure 1.3, Table 1.1).

**Table 1.1: Ren Property**

Tenure Number	Claim Name		Issue Date	Valid Until	Area (ha)
672243	REN 1		11/20/2009	20/11/2011	504.43
675463	REN 2		11/27/2009	27/11/2011	504.76

## 1.3 HISTORY AND PREVIOUS INVESTIGATIONS

Interest in the area was first sparked in 1905 when Cotton Belt Mines Ltd. discovered a stratiform magnetite-lead-zinc deposit, the Cottonbelt, just a few kilometres northwest of the Ren Property at Mount Grace (Höy, 1987; Gibson and Höy, 2007). This initial discovery was followed by years of intermittent surface and underground exploration on and around the Cottonbelt deposit that continued until 1929. Additional information about the history of the Cottonbelt and associated stratiform deposits around Mount Grace is available in Höy (1987) and Gibson and Höy (2007). Wheeler (1965) produced a map of the regional geology for the area, followed shortly by McMillan (1970, 1973), who carried out mapping projects on the west flank of the Frenchman Cap gneiss dome that resulted in the documentation of two types of carbonatites. Type I intrusive carbonatites were noted to have a metasomatized contact of variable extent,

being conformable to the bedding in their metasedimentary host rocks, and commonly contacting either a syenite or nepheline syenite gneiss. Conversely Type II extrusive carbonatites, believed to be of volcanic origin and lacking any kind of metasomatic boundary, were linked with the occurrence of a prominent marble horizon that was stratigraphically above the carbonatite bodies and used as a regional marker (McMillan, 1973; McMillan and Moore, 1974). Later mapping of the Mount Grace area by Höy and McMillan (1979) revealed that the discontinuous extrusive carbonatites of the Perry River area were likely related to the extrusive Mount Grace Carbonatite, which has a lateral extent of over 60 km. In 1983, Duval International Corporation conducted a geological and geochemical survey of their Ren I-IV claims that led to the discovery of the Ratchford Creek/Ren carbonatite; samples of the Ren carbonatite rendered anomalous values of niobium, cerium and lanthanum (Pilcher, 1983). Teck Exploration Ltd. carried out extensive work on carbonatites at Ratchford Creek in 1987, which included trenching and silt, rock, and soil sampling programs as well as radiometric and magnetic surveys (Betmanis and Lovang, 1988). Results from Teck's program indicated anomalous values of niobium and light rare earth elements. Further details about the Ren carbonatite and other occurrences along the west margin of the Frenchman Cap are available in McMillan (1970; 1973), McMillan and Moore (1974), Pilcher (1983), Höy and Kwong (1986), Höy and Pell (1986), Höy (1987), Betmanis and Lovang (1988) and Pell (1994). At the present these carbonatite exposures and associated alkaline rocks are contiguously staked along the western margin of the Frenchman Cap gneiss dome.

#### **1.4 PURPOSE OF WORK**

The purpose of the 2010 fieldwork was to perform preliminary prospecting of the Ren claims for any signs or exposures of economic mineralization and to document its location and exposed extent. Carbonatite hosted rare earth element (REE), niobium, and tantalum mineralization was of particular interest for this fieldwork.

#### **2.0 REGIONAL GEOLOGY**

The Ren Property sits along west margins of the Frenchman Cap gneiss dome on the eastern edge of the Shuswap Metamorphic Terrane (Figure 2.1); the oldest core gneisses have been constrained to an age greater than 2.1 Ga, while the youngest core gneisses have generated dates between 1.86 and 2.1 Ga (Armstrong et al., 1991; Crowley, 1997). Pell (1994) divides the

Canadian Cordillera into three distinct regions hosting carbonatites and alkaline rocks; of these three zones, the Perry River carbonatites belong to a western grouping, which occur within the Omineca Belt in association with core gneiss complexes deformed under upper amphibolite metamorphic facies during the Columbian Orogeny (Pell, 1994). The Monashee Complex, exposed within a tectonic window below a high angle thrust fault known as the Monashee Decollement, constitutes the core gneisses of the Ren Property and a succession of unconformable overlying autochthonous cover units (Read and Brown, 1981). These cover units host the extrusive Mount Grace Carbonatite, as well as intrusive carbonatites like those found on the Ren property and in the Perry River area, and syenite gneisses.

### **3.0 PROPERTY GEOLOGY**

Lithologies on the Ren claims consist of members belonging to the Monashee cover sequence described below in Section 3.1. Detailed petrographic descriptions of the Ren carbonatites and their associated rocks are available in Pilcher (1983) and Pell (1994).

#### **3.1 STRUCTURE, STRATIGRAPHY, AND LITHOLOGY**

The basement sequence of the Ren Property, along the northwestern border of the Frenchman Cap Dome is composed of a series of core gneisses that were structurally subdivided by Journeay (1982). Journeay's division, starting at the lowest stratigraphic unit, consists of paragneiss, an orthogneiss, and another paragneiss. Intercalated biotite paragneiss, semi-pelitic or pelitic schist, and quartzofeldspathic gneiss with local intrusions of superimposed potassium feldspar augen gneiss define the first paragneiss. The orthogneiss is identified by potassium feldspar augen gneiss, layered amphibolites, amphibole and orthopyroxene-bearing gneisses, alaskitic gneiss, a syenite gneiss, and a homogenous biotite gneiss that marks the upper boundary of the orthogneiss. The upper member of the core gneisses, a heterogeneous paragneiss, typically consists of biotite and quartz feldspar schists, amphibole and feldspathic gneisses, and amphibolite (Journeay, 1982; Höy 1987). Immediately overlying the core gneisses is an unconformable sequence of metasedimentary autochthonous rocks. The stratigraphic sequence for the Monashee cover suite in the areas of Mount Grace and Perry River is described as follows after Höy (1987), superseding the sequence described by McMillan (1973). Basal quartzites (Unit 3) lie directly above the core gneisses; these are comprised of successions of pure (ortho)

quartzites, feldspathic quartzites, and mica bearing quartzites with localized mica schists. Overlying the basal quartzites are a series of calcareous and pelitic schists, calc-silicate and paragneisses, impure marble, and the extrusive Mount Grace carbonatite layer that occurs in a subdivision of Höy's (1987) stratigraphic sequence (Unit 4c). A white calcite marble (Unit 5) that is used a regional marker is the next member of the sequence and may be underlain by quartzite or impure marble. The last member of the series (Unit 6), bounded at its upper surface by an unconformity, dominantly consists of pelitic schists with horizons of calc-silicate gneiss and rare quartzite layers.

The property and surrounding area have been subject to three episodes of penetrative deformation. The three episodes as characterized by McMillan (1973) and Journeay (1982) are: first generation east-verging, isoclinal and commonly shallow plunging folds; second generation west to southwest-plunging reclined folds and third generation east verging, northwest trending folds that post date metamorphism. The second-generation structures are the most prominent in the Perry River area as this second phase of deformation induced widespread interference patterns and subsequent z-folds (McMillan, 1973). Evidence of the Mount Grace syncline, a regional first generation fold, is also observable throughout the region. A major reverse fault, the Monashee Decollement sits a few kilometres west of the property, running along the west margin of the Frenchman Cap dome. This west-dipping, high-angle thrust fault separates the Monashee Complex from allochthonous cover that likely moved eastward along the Columbia River Fault Zone during the late Jurassic (Read and Brown, 1981). A series of late stage normal faults, post dating prior deformation and related to a period of crustal extension, trend north throughout the Monashee Complex. Movement along these faults is typically small on the regional scale but some, like the Perry River Fault, can exceed displacements of a kilometre.

## 4.0 EXPLORATION

### 4.1 ROCK SAMPLES

Dahrouge Geological Consulting Ltd. collected a total of 26 chip samples, 2 float samples, and 1 talus sample from the Ren Property and adjacent un-staked tenures as part of a preliminary prospecting program (Figure 4.1). Samples were collected through a combination of foot traverses, ATV surveys and helicopter support that was provided by LR Helicopters of Calgary, Alberta. The coordinates of every collection site were recorded from a handheld Garmin GPS

MAP 60 and accompanied by structural measurements (magnetic declination of 17.5° E) where outcrop exposures permitted. Lithologies sampled from the Ren property include carbonatite, fenite, marble and skarns. 5 samples (10-REN-079-1, 10-REN-079-2, 10-REN-079-3, 10-REN-118-1 and 10-REN-121) were selected for detailed petrographic studies conducted at the University of British Columbia in order to determine which minerals host the REE, Nb and Ta in these rocks. All samples were sealed in plastic bags and placed into pails for shipping to Acme Analytical Laboratories Ltd. in Vancouver, British Columbia. The samples were prepared according to Acme's R200-250 protocol; prepared samples were fused with lithium metaborate and dissolved in nitric acid prior to whole rock analysis of major and trace elements using ICP-MS, ICP-ES, and LECO (Acme 4A 4B). Analysis of base metals and precious metals, such as Ag, Au, As, Sb, Bi, Tl, Se, and Hg was carried out using ICP-MS according to Acme's 1DX protocols. Acme's analytical certificates are provided in Appendices 2 and 3.

## 5.0 RESULTS AND RECOMMENDATIONS

Several of the samples collected from the 2010 field program show encouraging results. Total rare earth element, niobium, and yttrium (TREE, Nb, Y) content are summarized in Table 5.1. The samples that returned the best values are highlighted in Table 5.1. Sample 71748, collected from a calcite-amphibole skarn, had the highest TREE content (1.5 %) of all samples collected and is highlighted in green. It also assayed an anomalous 250.5 ppm of Th. Sample 10-REN-079-2, a fenite, and 71736 collected from a fenite/carbonatite contact zone, returned the next highest results. Further work on the Ren Property should include a regional sampling and prospecting program focusing on establishing the extent of individual carbonatite bodies and their mineralization.

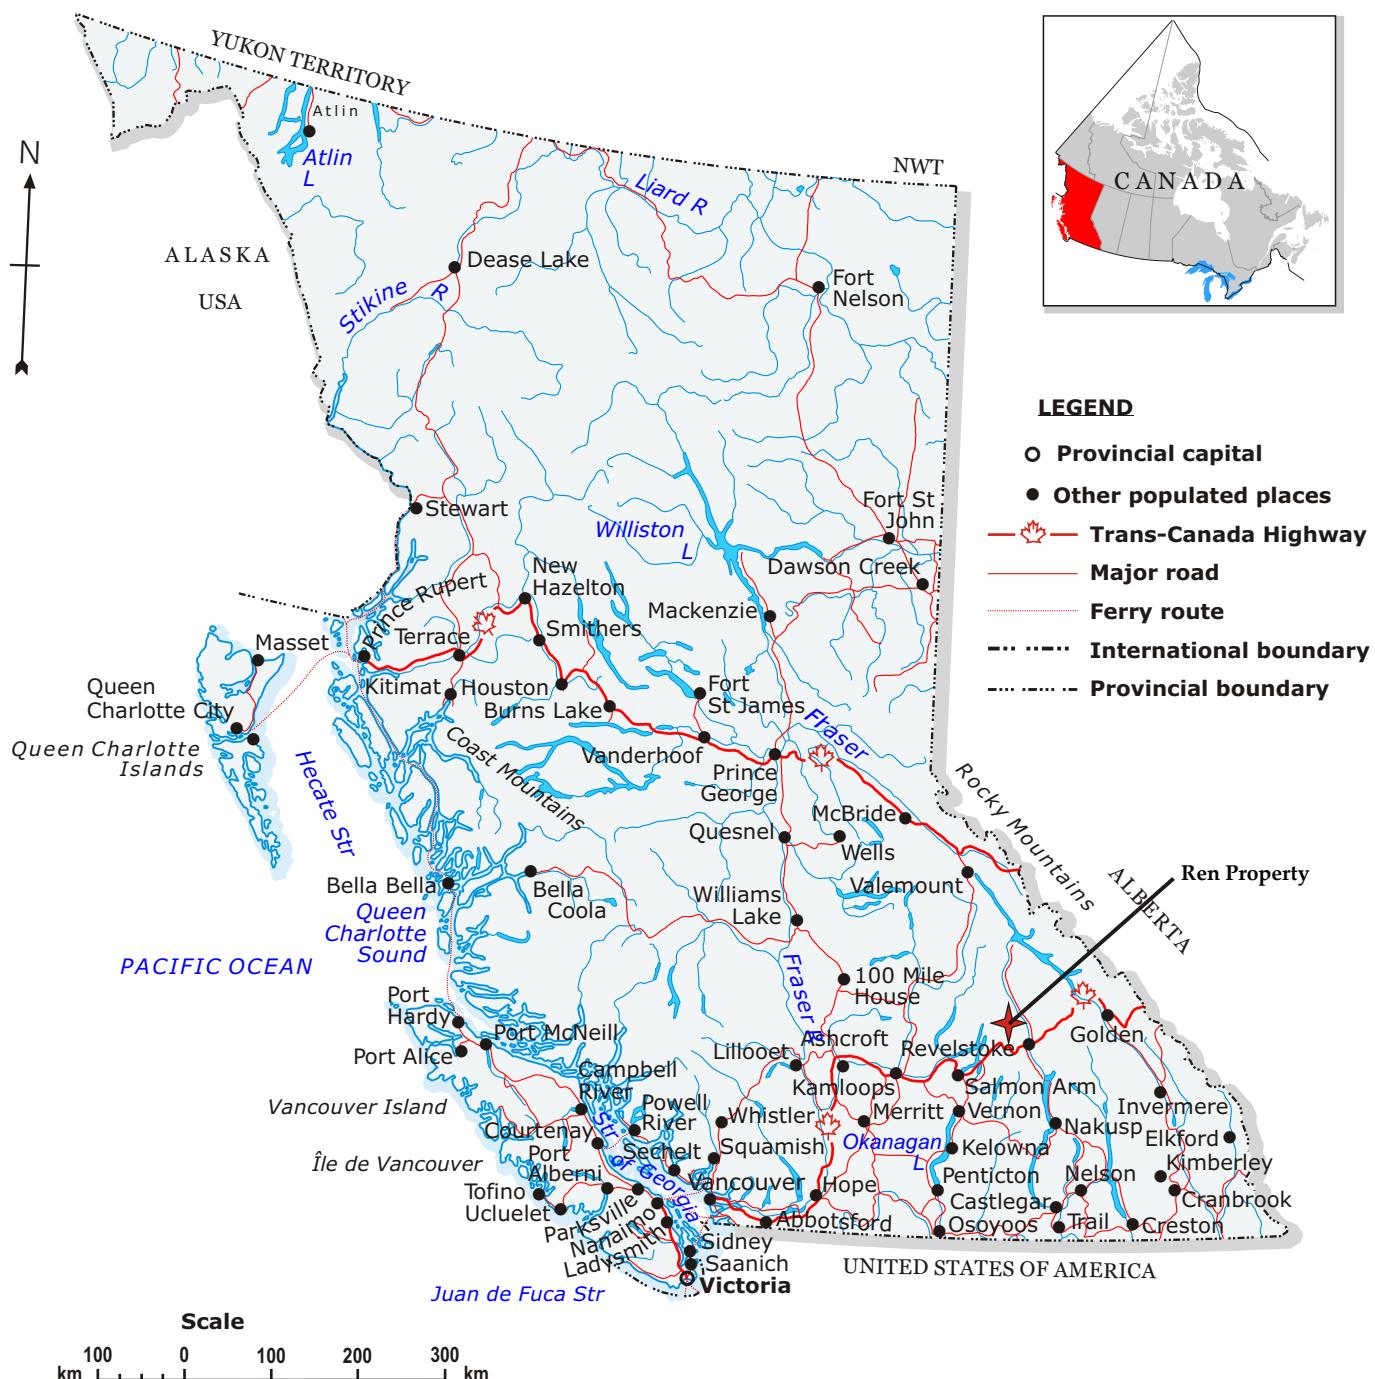

Table 5.1: TREE + Y and Nb Content Of Ren Samples

Sample	TREE+Y (ppm)	Nb (ppm)	Sample	TREE+Y (ppm)	Nb (ppm)

CC:

This report supersedes all previous preliminary and final reports with this file number dated prior to the date on this certificate. Signature indicates final approval; preliminary reports are unsigned and should be used for reference only.  
All results are considered the confidential property of the client. Acme assumes the liabilities for actual cost of analysis only.  
\*\* asterisk indicates that an analytical result could not be provided due to unusually high levels of interference from other elements.

## CERTIFICATE OF ANALYSIS

VAN10005282.1

### CLIENT JOB INFORMATION

Project: ZIMTU 2010  
Shipment ID:  
P.O. Number  
Number of Samples: 114

### SAMPLE PREPARATION AND ANALYTICAL PROCEDURES

Method Code	Number of Samples	Code Description	Test Wgt (g)	Report Status	Lab
R200-250	114	Crush, split and pulverize 250 g rock to 200 mesh			VAN
4A4B	114	Whole Rock Analysis Majors and Trace Elements	0.2	Completed	VAN

### SAMPLE DISPOSAL

RTRN-PLP Return  
RTRN-RJT Return

### ADDITIONAL COMMENTS

Acme does not accept responsibility for samples left at the laboratory after 90 days without prior written instructions for sample storage or return.

Invoice To: Zimtu Capital Corp.
