Grade - Recovery Curves	13
Flotation Report Sheets	14 - 33

INTRODUCTION

This report covers the preliminary flotation testwork on two separate composites of ore from the Harper Creek Copper Property in British Columbia.

Composite A, containing 68 pounds of crushed diamond drill cores, was received on December 3, 1970.

Composite B, containing 300 pounds of crushed cores, was received on January 14, 1971. This sample consisted of six bags designated as follows:

DRILL HOLE NO. 5

- No. 1 (69H-19, 69H-8, 69H-22)
- No. 2 (67H-1, 69H-5, 67H-2)
- No. 3 (69H-3, 67H-6)
- No. 4 (69H-1, 69H-6)
- No. 5 (69H-13, 69H-15)
- No. 6 (69H-27, 69H-23)

Each composite was screened at four mesh and the oversize crushed to minus four mesh. Head sample of each composite analysed as follows:

CONCLUSIONS

1. GRINDING REQUIREMENTS

Both composites were found to exhibit a considerable degree of kaolinisation with the result that the ore was quite friable and relatively easy to grind. A series of grinding tests are summarized below and the work index for each grind is given in comparison to McIntyre gold ore (work index 13.4).

Per Cent Minus 200 Mesh in Product	Laboratory Grind Time (Mins.)	Work Index (kwhr./ton)
50	4.4	8.7
60	6.0	9.6
70	7.9	10.4
80	10.1	11.1
90	13.8	11.9

Flotation testwork (See Test H-31) indicated that a primary grind to about 62 per cent minus 200 mesh should be adequate for this ore.

The power requirements for grinding are calculated from the following data:

Work index at 62 per cent minus 200 mesh = 10 kwhr./ton
80 per cent passing size of feed = 12,000 microns ($\frac{1}{2}$ ")
(assuming approx. rod mill feed)
80 per cent passing size of product = 132 microns

Using Bond's formula,

$$W = W_I \left(\frac{10}{\sqrt{P_{80}}} - \frac{10}{\sqrt{F_{80}}} \right)$$

$$\text{Power requirements} = 10 \cdot 10 \left(\frac{1}{\sqrt{132}} - \frac{1}{\sqrt{12000}} \right)$$

Power requirements = 8.2 Kwhr./ton *7.87*

2. RECOVERY OF COPPER

The best test results achieved on a sample of Harper Creek ore are shown below:

TEST H-31

Product	% Wt.	Assays		Distribution	
		% Cu	% Mo	Cu	Mo
2nd Clr. Conc.	1.2	27.63	0.020	78.7	5.8
2nd. Clr. Tail	0.3	8.20	0.091	5.8	6.4
1st. Clr. Conc.	1.5	23.75	0.034	84.5	12.2
1st. Clr. Tail	3.6	0.70	0.049	6.0	42.2
Rougher Conc.	5.1	7.48	0.045	90.5	54.4
Rougher Tail	94.9	0.042	0.002	9.5	45.6
Head	100.0	0.42	0.004	100.0	100.0

Behavior of
As?
Zn?

	<u>Composite A</u> (as per cent)	<u>Composite B</u> (as per cent)
Cu	0.46	0.42
Cu (as oxide)	0.012 ^{2.6%}	0.015 ^{3.6%}
Mo	0.016	0.017
Pb	<0.01	0.006
Zn	0.03	0.032
Ni	0.03	0.068
As	0.10 	0.01
Sb	0.01	0.012
Fe	4.8	4.2
S	1.69	1.66
Au	0.002 (oz./ton)	0.004 (oz./ton)
Ag	0.07 (oz./ton)	0.12 (oz./ton)
Py	4.80	3.23
Po (Magnetite) ^{? pyrrhotite}	3.38	-
CaO	3.8	1.5
MgO	3.2	1.8
Al ₂ O ₃	9.82	3.5
SiO ₂	63.0	60.9
Insol.	79.8	79.5
Specific Gravity	2.78	2.85

From the grade-recovery curves on page 13 the above test results are equivalent to a final concentrate grade of 25.00 per cent copper at a recovery of 82.8 per cent. Recirculation of cleaner tailings would probably increase the overall recovery to at least 85 per cent.

Testwork has shown the following factors to be of importance in the treatment of Harper Creek ore:

- 1) The copper in Harper Creek ore is present in the form of fairly coarse grained chalcopyrite with minor amounts of bornite and covellite.
- 2) Testwork has shown a primary grind to about 62 per cent minus 200 mesh to be adequate for achieving overall copper recoveries of 91 to 92 per cent in a rougher concentrate assaying approximately 7.5 per cent copper.
- 3) Reagent requirements appear to be relatively simple. Acceptable results were achieved using:

0.10 lb./ton R-343	- Rougher stage
0.03 lb./ton MIBC	- Rougher stage
0.02 lb./ton Sodium Cyanide	- Regrind stage <i>Zn/Py depression</i>
0.01 lb./ton S-3302	- Regrind stage
0.5 lb./ton Lime	- Regrind stage
- 4) Regrinding of the rougher concentrate was proved to be necessary for achieving high recoveries in the cleaning stages. Two stage cleaning was used throughout.

5) Flotation times were:

Rougher stage - 8 mins.

1st. Cleaner stage - 5 mins.

2nd. Cleaner stage - 4 mins.

- 6) Recovery of molybdenum, as can be seen from the metallurgical balance above, proved difficult. Even when specific molybdenum collectors were used (See Tests H-22 to H-24), low grades and recoveries were recorded. More work will be done on improving the molybdenum metallurgy.

TESTWORK PROCEDURE AND RESULTS

Testwork on Composite A (0.47 per cent copper)

A series of grinding and flotation tests were performed on 2,000 gram samples of Composite A to determine the optimum grinding time. A rougher concentrate was floated for four minutes using 0.10 pound per ton of AF-238 (sodium di-secondary butyl dithiophosphate). An additional 0.05 pounds per ton of AF-238 was added and a scavenger concentrate was floated for six minutes. Methyl isobutyl carbinol (M.I.B.C.) was used as the frother. The samples were treated at the natural pH of the ore which was 8.4. The results are tabulated below:

Test No.	Grind Time (Mins.)	%-200 M. in Product	O'All Rghr. + Scav. Conc. (% Cu)	O'All Rghr. + Scav. Recovery (%)
H-5	4	46.2	7.87	80.1
H-1	8	69.0	9.63	94.0
H-2	12	85.4	9.78	92.4
H-3	16	92.6	9.04	96.0
H-4	20	96.4	10.42	93.8

Testwork on Composite B (0.42 per cent copper)

The initial testwork on Composite B involved substantiating the earlier grinding tests performed on Composite A. Tests H-13 and H-14 were.

conducted on samples ground for sixteen minutes to 91 per cent minus 200 mesh. Using a similar procedure to test H-3, a comparison was made of the suitability of a xanthate collector, R-350, to the Aerofloat collector (AF-238) used previously. The results are summarized below:

Test No.	Collector Addition (Lb./ton)	O'All Ro + Scav. Conc. (% Cu)	O'All Rec. in Rghr. + Scav. Conc. (%)
H-13	0.15 AF-238	8.22	95.3
H-14	0.15 R-350	7.54	95.3

The results showed AF-238 to be slightly more selective than R-350.

A series of tests, H-15 to H-17, were carried out at varying grinds to further study the relationship between recovery of copper and fineness of grind. In each test a rougher concentrate was floated for eight minutes using 0.10 pounds per ton of AF-238. Two stage cleaning was employed, lime being added to maintain a pH of 10.5 in the first cleaning stage. The results follow:

Test No.	Grind Time (Mins.)	% -200 M. In Product	Ro. Conc. (% Cu)	% Recov. In Ro. Conc.	2nd. Cl. Conc. (% Cu)	% Recov. in 2nd. Cl. Conc.
H-15	6	53	7.74	83.9	14.25	75.7
H-16	9	71	8.61	90.7	13.57	86.5
H-17	12	83	8.32	93.2	14.82	84.7

The results at this stage indicated that a grind to between 70 and 80 per cent minus 200 mesh was probably optimum but cleaning of the rougher concentrates produced unacceptable grades of cleaner concentrates. Microscopic examination of the second cleaner concentrates showed the presence of large quantities of liberated pyrite with substantial amounts of quartz containing chalcopyrite inclusions.

For more effective depression of pyrite in the roughing stage, 0.5 pounds per ton of lime was added to the primary grinding stage in tests H-19 and H-20 to give a rougher pH of 9.5. Separate rougher and scavenger floats were carried out, with the first scavenger concentrate recycled to the succeeding rougher float of the double locked test. Two stage cleaning was again employed with additional lime being added to maintain a pH of 10.5 in the first cleaning stage. Test H-20 repeated the procedure of test H-19 with the exception that the rougher concentrate was reground. The results are given below:

Test No.	O'All Ro. + Scav. Conc. (% Cu)	O'All Recov. in Ro. + Scav. Conc.	2nd. Cl. Conc. (% Cu)	% Recov. in 2nd. Cl. Conc.
H-19	8.93	91.5	28.28	69.3
H-20	9.98	86.8	30.90	77.8

The results showed that:

- 1) Lime, added to the primary grind, was not effective in depressing pyrite in the roughing stage (compare tests H-17 and H-19).
- 2) Regrinding of the rougher concentrate gave substantial improvements in both grade and recovery of copper in the second cleaner concentrate (See grade-recovery curves on page 13.)

The preceeding testwork results showed on average approximately 20 per cent of the molybdenum had been recovered in a rougher concentrate which analysed only 0.026 per cent molybdenum, from a head grade of 0.005 per cent. Attempts were therefore made to increase the molybdenum recovery by the use of specific molybdenum and copper/molybdenum collectors.

Tests H-22 to H-24 involved the use of fuel oil and Cyanamid reagent S-3302 as molybdenum promoters. The results (See Flotation Report Sheets on pages 14 to 35) showed the highest molybdenum content in a second cleaner concentrate to be 0.072 per cent at a recovery of 17.2 per cent. As the results were disappointing, attention was paid to improving the copper metallurgy in the remaining tests covered by this report.

The results of test H-24 showed an overall copper recovery of 90.9 per cent at a grind of 57 per cent minus 200 mesh. The remaining test-work on Composite B was therefore aimed at producing an acceptable grade of

cleaner concentrate at this grind. Tests H-26 to H-31 involved the regrinding of rougher concentrates with combinations of lime and sodium cyanide. The results are shown in the grade-recovery curves on page 13.
