SUMMARY OF CONCLUSIONS AND RECOMMENDATIONS

The Bar joint venture property is underlain by volcanic and sedimentary rocks similar in nature to those found in many massive sulphide camps worldwide. The presence of alteration and mineralization in several places is indicative of widespread hydrothermal activity. In addition, direct comparisons may be made with host rock sequences of the Rea Gold and Homestake deposits immediately to the southeast of the property.

Seven areas of the property are targeted for further exploration. Two of these involve diamond drilling as the next step and have excellent potential for an immediate discovery. The rest require more detailed geology, geophysics and geochemistry initially. Other target areas are expected when all lithogeochemical data has been received and analyzed. A specific work programme outline is deferred until this has been done.

INTRODUCTION

Corporation Falconbridge Copper acquired 453 claim units (Bar, Alex, Anna and SC) in the Kamloops Mining Division, British Columbia between November 1, 1983 and May 1, 1984. Under an agreement dated July 2nd, 1984, Corporation Falconbridge Copper and Rea Gold Corporation formed a joint venture to explore these claims, collectively termed the Bar Project.

The terms of the agreement allow Rea Gold Corporation to obtain a 45% interest in the property by spending \$1,000,000 on exploration on the property before January 1st, 1987. CFC is operator.

This report presents the results of work carried out during 1984 and outlines preliminary conclusions and recommendations designed to optimize the chances of early discovery and ensure thorough coverage of this large property.

PROPERTY AND OWNERSHIP

Figure 1 shows the configuration of the Bar, Alex, SC and Anna claims. They consist of 463 claim units covering approximately 11,300 hectares. Table 1 summarizes the pertinent claim data. All are 100% owned by CFC, however the Anna claims are subject to a 5% royalty on the net proceeds of production payable after recovery of exploration, pre-production and capital expenditures.

SC7	5907	6	October	1985

Sufficient assessment work has been or will be filed to maintain all claims.

LOCATION AND ACCESS (Figure 2)

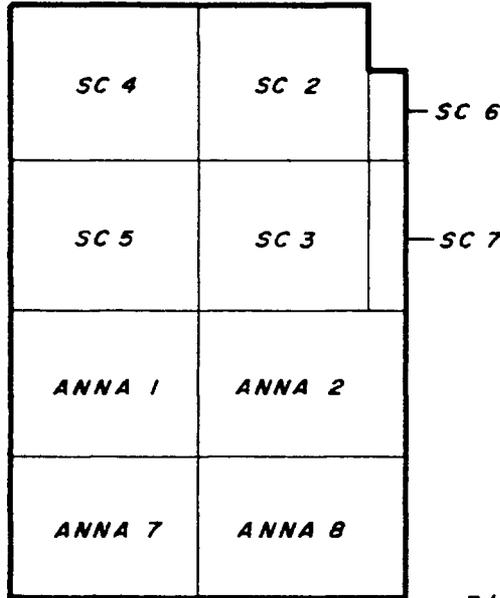

The claims are located on the Adams Plateau between Adams Lake and North Thompson river and are bounded by latitude $51^{\circ}00'N$ and $51^{\circ}25'N$ and longitude $119^{\circ}45'W$ and $120^{\circ}10'W$ (Figure 2).

Access is readily available from Highway 5 in the Barriere area. Principal routes are via the Skwaam Bay Road, Dixon Mountain Road and

Barriere Lakes Road. From these numerous logging roads provide 4X4 access to most parts of the property.

PHYSIOGRAPHY

The western edge of the Adams Plateau consists of high rolling plateau country incised by locally steep drift filled valleys. Elevations range from less than 500m. in the Sinmax Valley at the south end of the property to over 1900m. on the SC claims. However, the majority of the property lies between 1000m. and 1500m. elevation.

Fairly dense forest cover occurs across most of the area, although the Sinmax Valley is partially cultivated. Active logging operations are present on the property.

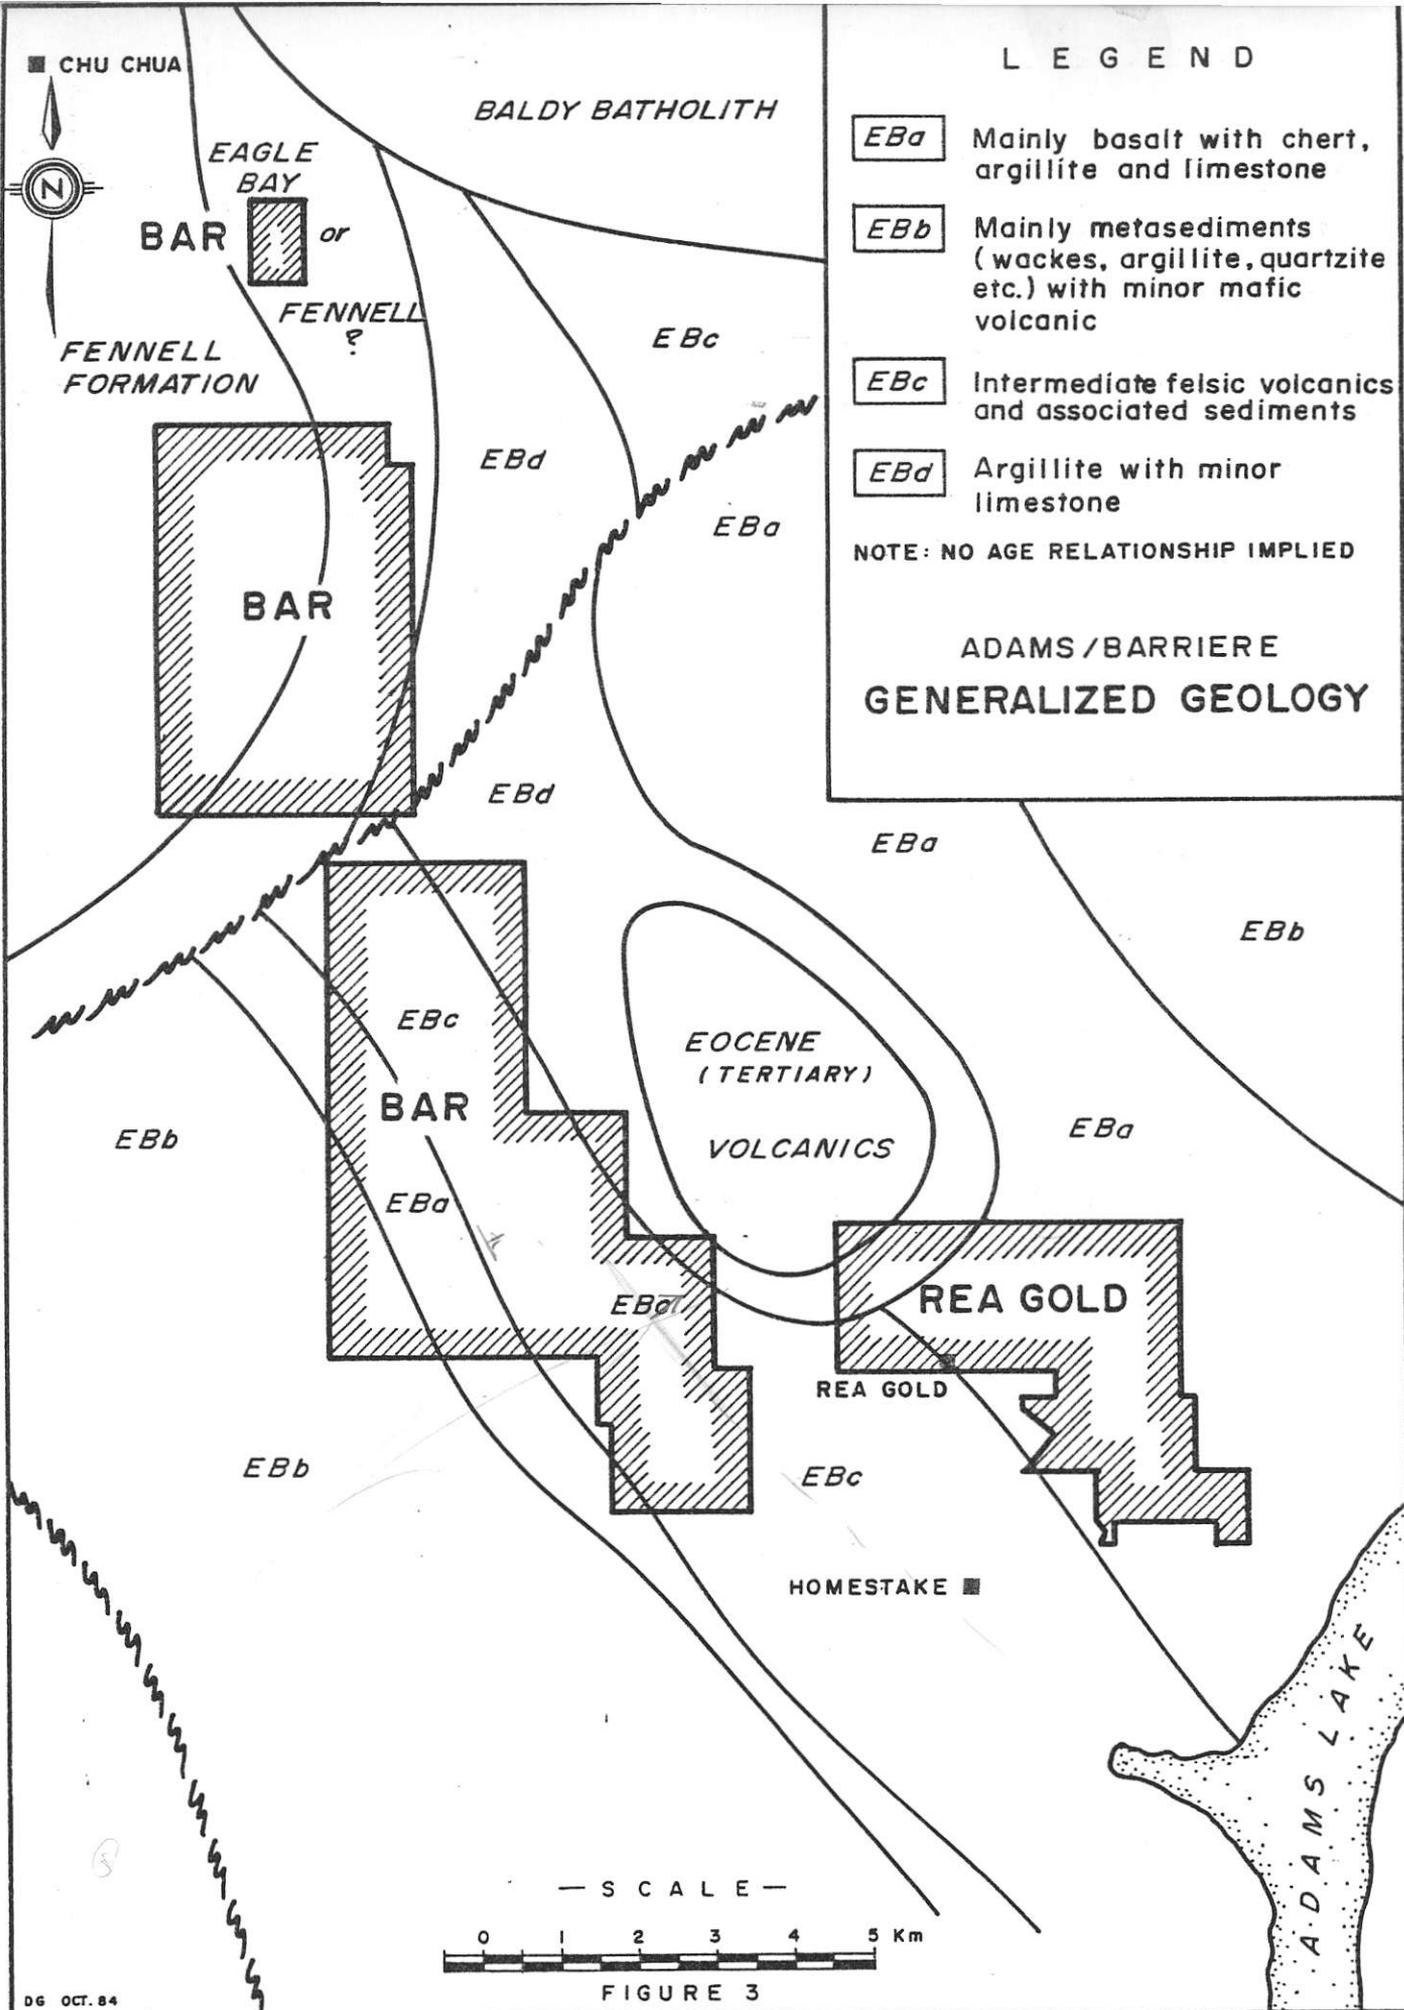

The climate is moderate with temperatures ranging from -25°C in the winter to $30^{\circ}\text{C}+$ in the summer. Precipitation is extremely variable ranging from semi-arid in the south to moderately wet in the north. The snow free period runs from May to November in the south, but lasts only from July to October in the north.

REGIONAL GEOLOGY (Figure 3)

The Adams-Barriere region has been mapped by a number of government workers, most recently by Preto et al (1977-1981). Their preliminary geology map (No. 56) has recently been released by the B. C. Ministry of Energy Mines and Petroleum Resources.

The region is underlain by weakly metamorphosed and moderately deformed volcanic and sedimentary rocks of Late Devonian to Early Carboniferous (Mississippian) age which have been intruded by granodiorites and monzonites, mostly of Cretaceous age. The volcano-sedimentary rocks are divided into the Fennell Formation and the Eagle Bay Formation.

The Fennell formation consists of submarine basalts and mafic intrusions with minor chert, sediment and felsic intrusions and volcanics. It has been interpreted as having formed in a volcanic island-type environment

L E G E N D

- EBa Mainly basalt with chert, argillite and limestone
- EBb Mainly metasediments (wackes, argillite, quartzite etc.) with minor mafic volcanic
- EBc Intermediate felsic volcanics and associated sediments
- EBd Argillite with minor limestone

FIGURE 3

by Aggarwal (1984). The Fennell Formation hosts the Chu Chua deposit which contains 2.6 M tons of 2.0% Cu and 0.25 oz/t Ag and is a basalt hosted syngenetic massive sulphide.

The Eagle Bay formation can be divided into four main packages:

- a) a predominantly mafic volcanic package with chert, argillite and limestone (EBa);
- b) a predominantly sedimentary package (greywackes, argillites, quartzite etc). with minor mafic volcanics (EBb);
- c) an intermediate - felsic volcanic package with associated sediments (EBc);
- d) a sedimentary package comprised of argillites with minor limestones (EBd).

Just how these packages inter-relate has yet to be conclusively determined but all are consistent with depositional environments which might be found in an oceanic area flanking a volcanic island or island-arc.

Mineralization is largely confined to packages EBa and EBc. The mafic volcanics and associated sediments host numerous stratabound and vein occurrences, particularly east of Adams Lake. Most are Pb-Zn-Ag with limey hosts. The more felsic package contains the Homestake Ba-Ag-Pb-Zn deposits as well as numerous Cu-Pb-Zn occurrences. The Rea Gold Au-Ag-Ba-Pb-Zn-Cu deposits are close to the transition between the two packages.

The Eagle Bay formation is in part coeval with and in part overlies the Fennell Formation. The Bar Property lies entirely within the Eagle Bay south of the Barriere River, but straddles the contact between the Eagle Bay and the Fennell north of the Barriere River.

The major intrusive body in the area is the Cretaceous Baldy batholith. It causes a major disruption in the northwest continuation of the Eagle Bay formation, but has no obvious effect on the rocks of the property area.

Also present, between the Johnson Creek and Barriere River valleys is a basin containing Eocene andesites and basalts assigned to the Kamloops Group. These cover the Palaeozoic stratigraphy immediately east of the southern Bar claims.

Structural features of the region include at least two phases of folding and faulting. These can be readily seen on the outcrop scale, but are hard to delineate on the regional scale because of the discontinuous nature of rock types and locally poor outcrop.

PREVIOUS WORK

Although the Adams-Barriere area has seen a moderate amount of exploration over the years, very little previous exploration has been recorded on the Bar Property area. South of the Barriere River the only filed assessment is for the southern half of the Bar 1 claim (see Figure 1). There, Cominco carried out a minor amount of geology and geochemistry in 1977 without significant results (Wodjak, 1977). There is also evidence of a fairly old grid in the area SE of Dixon Lake, but its origin and raison d'etre are unknown at this time.

North of the Barriere River the entire property is covered by a 1978 Craigmont Dighem airborne survey. It shows numerous conductors and was used, to a certain extent, by CFC to choose areas for staking. Most of the conductors have never been located or tested on the ground. A limited area on the eastern side of the Anna and southern SC claims was covered by EM-16, Mag and soils (Vollo, 1981). This data will be integrated with our own.

A group of claims known as the Enargite claims are adjacent to and partly overlap claim SC1. Although very little data is available on them, Min-File lists past production of 5 tons of ore from sulphide pods in quartz

veins cutting sediments. Minor amounts of lead, zinc and silver were recovered.

CFC - 1984 PROGRAMME

The following exploration work was carried out by CFC during 1984:

DigheM Airborne Survey	400 km	covered the property south of the Barriere River, not previously covered by Craigmont.
Stream Sediment Sampling	38 samples	heavy mineral separates analyzed for Au + 26 element ICP and compared to Rea Gold area orientation.
Semi-detailed Reconnaissance Mapping and Lithochemical Sampling	322 samples 240 man-days (approx.)	tying together geology and prioritizing targets.
Linecutting	45 km	Dixon Lake Area
Geophysics	38.5 km	two station VLF, Dixon Lake grid
Soil Sampling	873 samples	Dixon Lake grid covered at 50m. intervals with 25m. samples every 10th line.
Litho Sampling	212 samples	available outcrop sampled at approx. 50m. intervals

methods. A notable example of this is Equity Silver's Sam Goosly deposit, the discovery of which is attributed to a HM stream sediment survey in an area previously sampled by numerous exploration companies using normal methods.

Since the Bar property is so large and drained by numerous creeks it was decided to carry out such a survey. Consequently 31 samples were taken from various points on and around the property along with 7 orientation samples from creeks draining the Rea Gold property (Map 1a). Samples were analyzed for Au, total Ba and a 26 element ICP package.

The results are shown in symbol map form (Maps 1b-d) for the elements Au, Ag, Cu, Pb, Zn, As, Sb and Ba. Other elements are not considered important at this time, although they may be plotted at a later date. All data is presented in Appendix L.

Au, Ag (Map 1b)

Both Au and Ag are quite highly anomalous in Homestake Creek and in two small creeks draining the Rea Gold area. Johnson Creek, some distance from known mineralization, is moderately anomalous and even the upper reaches of Homestake Creek show anomalous values.

On the Bar property, areas immediately north of the Dixon Lake valley and at the extreme north end of the property stand out as highly anomalous in terms of Au values. In fact 3 of the creeks show values (900, 930 and 1100 ppb) greater than or equal to the best of the creeks draining Samatosum Mountain (900 ppb). Ag also highlights the north end of the property.

Areas with lower, but still anomalous Au values include the Alex Creek area at the south end of the property, the south slope of the Dixon Lake valley and the north slope of the Barriere River.

Ba, As, Sb

All creeks sampled on Samatosum Mountain were anomalous in Ba. Homestake Creek and one of the Rea Gold area creeks are anomalous in As while only the former is anomalous in Sb.

On Bar, Ba and As again highlight the extreme north end of the property and also the Alex Creek area. Arsenic is anomalous in two creeks draining into the Barriere River, one from the north slope and one from the south. Sb anomalies suggest a source near the watershed between Dixon Lake and the Barriere River.

Cu, Pb, Zn

All creeks on Samatosum Mountain except one of the Rea Gold area creeks were anomalous in Cu, Pb and Zn.

One again, on Bar, the north end of the property is highlighted, along with Alex Creek. Otherwise only two isolated anomalies (one in Cu, one in Pb) in creeks not anomalous in anything else, were found.

Geology (Maps 2a-d)

During the course of the 1984 field season, the entire property area was geologically mapped at the semi-detailed scale of 1:10,000. Although a lack of outcrop in a few areas hampered the mapping, sufficient exposure generally exists to allow fairly good stratigraphic correlations to be made.

South of the Barriere river (Maps 2a,b) the property is underlain by a NW trending, usually easterly dipping, sequence of volcanics and sediments. Although they are locally folded (especially the sediments) they have good continuity and are believed to young eastwards.

The oldest exposed rocks on the property are greywackes with minor chert, limestone and mafic volcanics. These correspond to package Ebb on

the Regional Geology map and are considered to be of low exploration potential.

Immediately overlying the sediments is a heterogeneous sequence of alkaline basalts, including flows and pillowed flows, tuffs, lapilli tuffs and related sediments and intrusions. They are often strongly magnetic and may be variolitic and vesicular. In the area south of Dixon Lake there is quite extensive quartz-carbonate veining and carbonate-sericite-pyrite alteration. These rocks correspond to package EBa on the regional map and are tentatively correlated with the footwall basalts on the Rea Gold property. They are considered to be on the upright limb of a regional fold. The Rea Gold property is considered to be on the recumbent limb.

Overlying the basalts is a mixed sequence of sediment and volcanics. The sediments include very coarse varieties (quartz-pebble conglomerates and quartzose grits), fine varieties (wackes and argillites) and chemical varieties (chert, very minor limestone) and are volumetrically dominant. The volcanics are basaltic tuffs and lapilli tuffs. Diorite intrusions are also common. These rocks are transitional between packages EBa and EBc and correspond to units mapped in and to the SW of the Rea Gold trenches area. These rocks are thus correlated with the mineralized sequence hosting the Rea Gold massive sulphides.

The youngest volcanic rocks exposed are intermediate to felsic pyroclastics. These have been traced from the Johnson Creek area in the extreme SE and are known to correlate with rocks hosting the Homestake deposits (package EBc). In the north-central part of the Bar claims considerable amounts of quartz-feldspar porphyry and enhanced thicknesses of the intermediate to felsic pyroclastics suggest a volcanic centre. However, active logging and poor exposure has not permitted full definition of this centre to date.

The youngest sediments exposed are argillites and greywackes of package EBd which underlie the extreme eastern parts of the property.

North of the Barriere river (Map 2c,d) units strike more or less north-south and generally dip steeply west to steeply east, but with extreme variability. Younging direction is, as yet, ambiguous.

These rocks may be divided into three groups. In the south and south-east a package of intermediate to felsic pyroclastics with coarse quartzose sediments may be confidently correlated with similar rocktypes on the property, south of the Barriere river. This is package EBC on the regional map and includes the Homestake stratigraphy.

The bulk of the claim group is underlain by a sedimentary package intruded by diorites and hosting a major felsic volcanic centre. The sediments tend to be predominantly cherty to the west and become argillitic to the east, with wackes in the centre. The volcanics consist of a quartz-feldspar porphyry (QFP) dome flanked by rhyolite flows and breccias. Folding is extensive within the package and local tops can be either east or west. However, it is currently felt that these rocks young eastward and are the time-stratigraphic equivalent of the Rea Gold and Homestake host rocks.

The western side of the property is underlain by a sequence of tholeiitic basalts and intrusions with very minor cherty tuffs. It is one of these cherty tuffs which, 4km north of SCl, hosts the 2 million ton Chu Chua cupriferous massive sulphide deposit. Although attention was focussed more on the felsic rocks during 1984, mineralized cherty tuffs and altered mafic volcanics were noted on the property.

The most significant mineralized area is undoubtedly related to the felsic volcanic centre mentioned above. The QFP dome is laced with pyritic stringers accompanied by sericitic alteration. In addition, sediments surrounding the centre have yielded exceptionally high Ba values (up to 20,000+ppm). In addition, sediments surrounding the centre have yielded exceptionally high Ba values (up to 20,000+ppm).

Lithogeochemistry

The last of the reconnaissance rock sample data has recently been received and computer entry is underway. This data will be analyzed, with very careful regard to geology, as time permits. A brief scan of raw data suggests numerous anomalous areas indicated by high Ba and trace element (Cu, Zn) values and depleted alkalis (Na_2O , CaO). A full analysis of these will be presented as soon as it is available. Raw data is included herein (Appendix 2, Maps 3a-j).

Dixon Lake Area - Detailed Work

Recognition that the stratigraphy in the Dixon Lake area is equivalent to that on the Rea Gold property was made quite early in the programme. Consequently a 45 km grid was established to allow detailed examination of some of the most interesting Digheem anomalies within this favourable sequence. Maps 4a,b, 5a-h and 6 present the results. Soil geochemical raw data is in Appendix 3. Lithogeochemical data has not yet been received.

The area gridded covers the contact between the basaltic volcanics in the Dixon Lake area and the sedimentary/volcanic package that is correlated with the mineralized sequence at Rea Golf.

The volcanics are very heterogeneous, ranging from flows and pillowed flows to tuffs and lapilli tuffs. Amygdules are common and usually carbonate and/or chlorite filled. Magnetite is abundant south of Dixon Lake. Like the footwall basalts on the Rea Gold option, Fe-carbonate is an abundant alteration product. It is often accompanied by sericite and quartz-carbonate veins and locally by up to 10% pyrrhotite. There is no doubt that hydrothermal systems were active within this unit on the Bar property.

The overlying sediment/volcanic package is rather poorly exposed in places, due to the recessive weathering of some of the sediments (as well as alteration zones and massive sulphides!) It consists essentially of quartzites and fine grained wackes north of Dixon Lake. Within these are basins of

chert, very similar to the Rea Breccia in character, and argillite. Several thin mafic tuffs and debris flows are also present. South of Dixon Lake, in the Mine Lake area, a very distinctive zone of quartzose grits and quartz pebble conglomerates is found in addition to the aforementioned rock types. Intruding all of these are plugs, dykes and sills of hornblende diorite and gabbro.

The overall geological environment on the grid is one of transition from basaltic volcanism to sedimentation in an oceanic basin.

Soil geochemistry shows numerous anomalies in all elements (Maps 5a-h). Two areas stand out in particular. These are both north of Dixon Lake, occurring NE of the baseline on lines 107-112 and 124-130. (They may, in fact, be a single zone since no data exists between those areas.) The areas are characterized by anomalous Au and Ag with smaller anomalies in Zn, Pb and As. Coincident VLF (and Dighem) conductors are also present (see Map 6).

Another area which stands out lies south of Dixon Lake at the SW end of lines 82-87. Although not coincident, anomalies in Cu, Zn, As, Ag, and Au occur in an area of VLF conductors and altered volcanics.

DISCUSSION OF RESULTS

The primary objective of the 1984 programme was to examine the Bar property in as much detail as possible to establish specific areas for more detailed work and eventual diamond drilling. This has been completed to the extent that specific target areas are now apparent and one area has been detailed to the point of having drill targets.

Geological mapping has confirmed the presence of subaqueous volcanics and sediments throughout the property. Moreover, the volcanics show the mafic to felsic range characteristic of many volcanogenic massive sulphide hosting sequences worldwide (Noranda, Kuroko, Kidd Creek, etc.). On a local scale, direct comparisons may be made with stratigraphy in the Rea Gold and Homestake deposit areas. The Rea deposits are hosted by chert and chert breccia in a transition zone between basalts and sediments, with minor

intermediate volcanics. The Homestake deposits are hosted by felsic volcanics. On the Bar property south of the Barriere River the basalt-sediment transition appears to be somewhat thicker than at Rea, but has definite chert basins. The presence of the Homestake felsics has been confirmed over a strike length of more than 10 km with a potential volcanic centre indicated on the property towards the north.

North of the Barriere River a similar mafic-sediment-felsic sequence has been outlined. Although it does not appear to correlate directly with the sequence to the south, it is believed to be a time stratigraphic equivalent. Several areas of cherty tuff similar to Chu Chua host rocks have been outlined within the basaltic package. The felsic rocks consist of QFP domes and associated extrusives, characteristic of a vent area, and flanked by cherts and argillites.

Alteration and mineralization are widespread throughout the Bar property. Most notable areas are within the basalts south of Dixon Lake (qtz-carb-py veins, carb-sericite alteration); within sediments NW of Dixon Lake (py-galena in veinlets), in cherty tuffs in the west-central part of the SC/Anna claims (pyritic); and in QFP in the area north of Sprague Creek (extensive qtz-py stockwork with sericitic alteration). Although none of these are by any means ore grade, they do indicate extensive hydrothermal activity. This hydrothermal activity, when combined with a favourable depositional environment (as indicated by mapped lithologies) is strong evidence for the presence of significant massive sulphide bodies.

The stream sediment survey succeeded in outlining at least three drainage basins worthy of further exploration. These basins are to the north of Dixon and Little Dixon Lakes; in the area of claim SC1; and the Alex Creek drainage area.

The area north of the Dixon Lakes includes both the Rea Gold and Homestake packages. In addition, several intriguing, isolated Dighem anomalies occur and anomalous soil geochem values have been obtained from these.

Alex Creek drains rocks of the Homestake sequence. There are also several isolated Dighem responses in the area.

SC1 has very limited exposure, however what there is is very revealing. Silicified basalts, cherts and angular chert breccias with abundant pyrite cross the area.

Detailed work in the Dixon Lake area has outlined three zones of soil and VLF anomalies in geologically favourable areas. Analysis of lithogeochemical data, when available, is expected to produce further targets.

CONCLUSIONS AND RECOMMENDATIONS

Final conclusions and recommendations for 1985 cannot be made until all lithogeochemical data is received and analyzed in conjunction with the geology. As well, compilation of the Dighem data with the recently completed geological base maps is unfinished. However, preliminary conclusions can be drawn which point to a very exciting and successful 1985 and 1986.

Prime target areas for follow up will include the following:-

1. North of the Barriere River

a) the felsic volcanic/QFP area towards the north end of the claims has areas of strong pyritic stockwork. Flanking sediments have yielded Ba values in excess of 20,000 ppm. This classic massive sulphide environment must be explored in detail and its Dighem anomalies tested.

b) mafic volcanics between Delta Creek and Bottrel Creek on the west side of the Anna claims are bleached and altered and host several cherty tuff horizons. At least 8 Dighem responses occur in the basalts or at their contact with chert to the east. This is

correlated with the Chu Chua massive sulphide deposit stratigraphy and is a must for follow up.

c) stream sediment anomalies from the SCl area require follow up. This will probably be in a fairly low key manner initially until the property can be expanded in that area.

2. South of the Barriere River

a) drill targets already exist in the area north of Dixon Lake. These must be tested in conjunction with expansion of the existing grid to the northeast to cover the anomalous Little Dixon Lake drainage basin and Dighem anomalies therein.

b) drill targets in the basalts south of Dixon Lake and at the contact with the overlying sediments near Mine Lake exist. These should be tested to determine the potential of this area and further work designed accordingly.

c) the potential felsic centre at the watershed between the Barriere River and the Dixon Lakes must be examined. Because of poor exposure and active logging this will probably take form of additional mapping and sampling initially.

d) the Homestake felsic sequence in the Alex Creek basin must be examined. Sources for the high stream sediment values will be sought and Dighem anomalies located.

All of this work cannot be undertaken under the current budget scenario. In the coming weeks targets will be refined and prioritized and a budget proposal submitted which will be designed for early discovery. This will be achieved by concentrating funds in the top priority areas with a large portion of them going into diamond drilling. At the same time, sufficient work must be carried out on other areas to cover assessment requirements.

ANALYTICAL REPORT

Project 215 Date of report June 25/84.

File No. 4-387 Date samples received June 15/84.

Samples submitted by:

Company: Corp. Falconbridge Copper

Report on: 18 HM Geochem samples

..... Assay samples

Copies sent to:

1. Corp. Falconbridge Copper, Delta, B.C.
2. M.Burson, Barriere, B.C.
3.

Samples: Sieved to mesh Ground to mesh

Prepared samples stored discarded

rejects stored discarded

Methods of analysis: HM-Specific gravity flotation and 26 ICP Analysis.

Total Ba-fusion.A.A., Au-aqua regia.A.A.

Remarks:

Dear Ian -

Sample BCS 2540 contains something non-volatile other than the elements we have analysed. We have run this one 3 times, always with the same results, but total oxides plus L.O.I. only add up to about 94%.

P_2O_5 maybe plus some other minor elements: Sr, Cr??

Yvonne
