An examination of the Pat claim was conducted by R. Walker, O. Bundred and G. Crowe of Westmin Mines Ltd. on the morning of November 1, 1989. New logging road access had reportedly exposed several copper showings.

Several outcroppings were examined and samples were collected from five areas of interest (see accompanying Figures and sample descriptions). In all, a total of 30 samples were taken from mineralized and/or altered outcrops.

Orange weathering carbonate alteration zones appear to be controlled by a northwest trending structure. In this area, basaltic tuffs, chert and minor limestone of the Sicker Group is interpreted to unconformably underlie Nanaimo Fm. sediments. The carbonate altered structure cuts this contact at a high angle.

Alteration consists of ankerite, silica, calcite +/- sericite. Several extensively weathered outcroppings contain a significant amount of clay. Disseminated pyrite and minor chalcopyrite are present locally.

Outcrops 1 and 2 (see accompanying map) cut ankerite altered Sicker tuffs, cherts and limestone. Disseminations and patches of pyrite and minor amounts of an unidentified silver grey sulphide were noted. Samples containing malachite returned up to 1254 ppm Cu with 30 ppb Au.

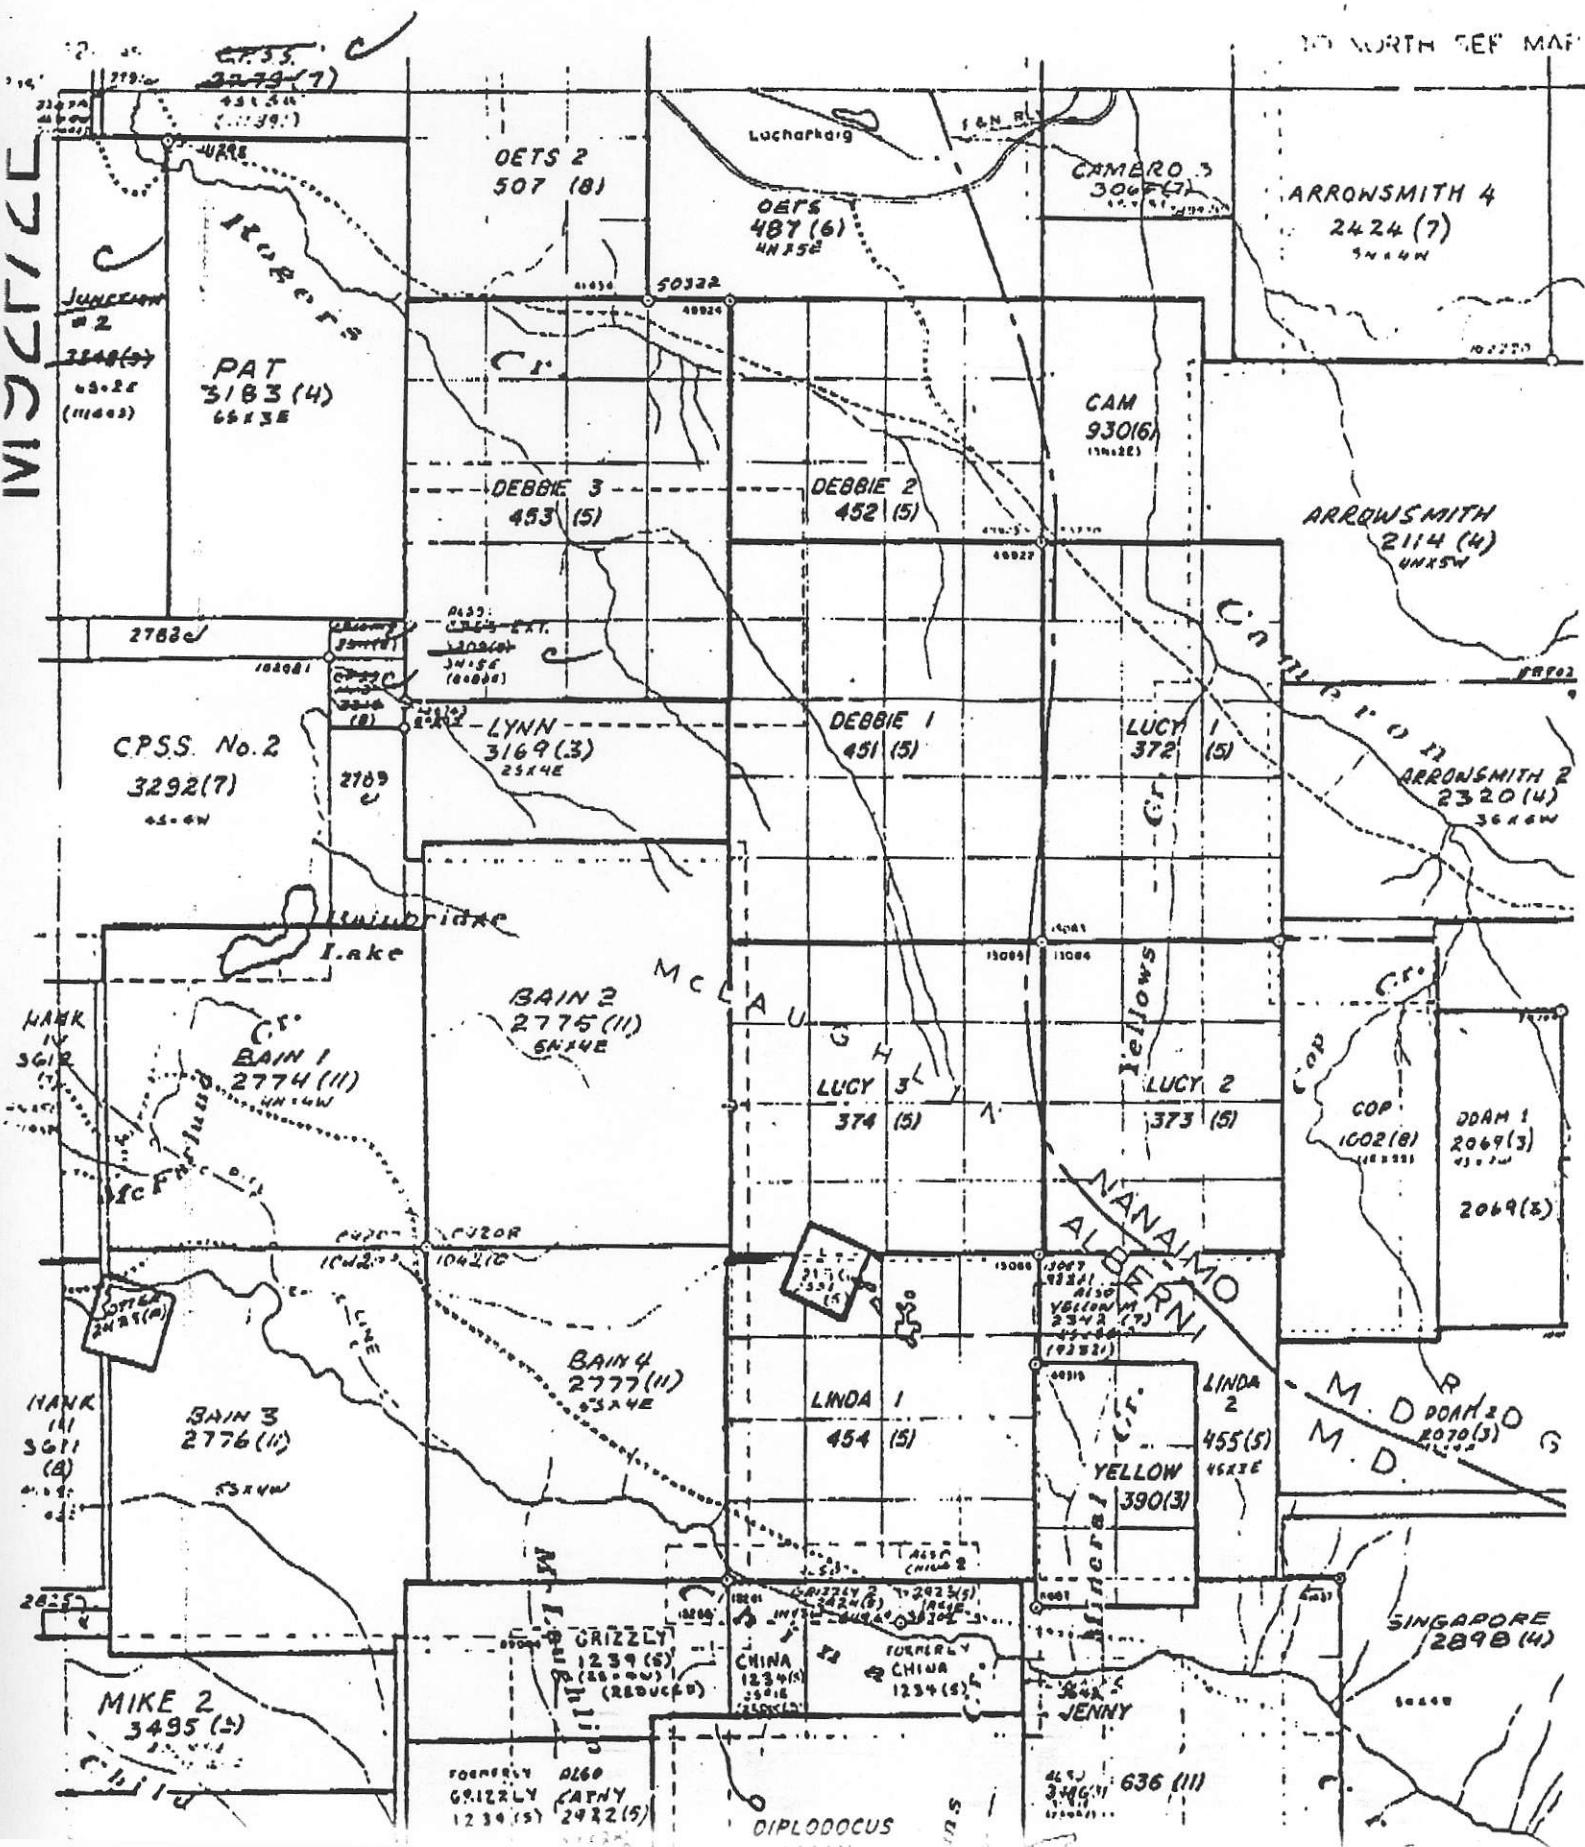

Outcrops 3 and 4 cut ankerite altered Nanaimo conglomerates and sandstones. Coarse vuggy quartz and/or sparry calcite veining is abundant. Patches and seams of an unidentified amorphous looking silver grey sulphide (possibly tetrahedrite) are locally associated with either the quartz or calcite veining. These samples returned up to 5380 ppm Cu, 45.8 ppm Ag, 570 ppm As and 2029 ppm Sb. No significant gold values were detected.

Outcrop 5 occurs several hundred metres to the south of outcrops 1 to 4. Here Sicker volcanics are cut by granitic intrusives. Quartz veining with abundant chlorite and/or epidote are hosted by ankeritized and/or clay altered intrusive and volcanics. Disseminations and patches of pyrite and minor chalcopyrite and malachite are present locally. Up to 6432 ppm Cu, 2.8 ppm Ag, 303 ppm Sb, 7526 ppm B have been returned from samples collected in this area. No significant quantities of gold were detected.

The elevated Cu, Ag, Sb, and B values suggest these ankeritized structures may be of interest with respect to gold exploration. These elements are known to be associated with epithermal gold systems. The low gold values in the samples collected however, suggest this property would not be of interest to Westmin at this time. Should further development of the property yield a more favourable gold environment, Westmin should consider picking up the property at that time.

Gregory G. Crowe, M.Sc., P.Geol.
