SUMMARY AND CONCLUSIONS

1. The Hearne Hill claims of Booker Gold Explorations Limited are situated in the Babine Lake district of British Columbia, 65 kms. northeast of Smithers.
2. The property is underlain by volcanic rocks belonging to the middle Jurassic Hazelton group, which consist principally of water lain grey lapilli crystal tuffs and grey andesites, with some associated sedimentary rocks (principally gritty greywackes, siltstones and buff felsic tuffs).
3. The volcanic sequence has been intruded by porphyritic intrusions of approximately 50 million years age which belong to the Tertiary-Eocene Babine igneous suite.
4. Associated with the Babine intrusives on the Hearne Hill property are two types of copper, molybdenum, gold, silver deposits, as follows:
 - a. a stock work porphyry-copper of the general Babine type;
 - b. a breccia pipe situated within the porphyry deposit which contains high-grade copper-gold mineralization.
5. In the stock work copper/molybdenum porphyry deposit, chalcopyrite, pyrite and molybdenite occur in fracture fillings, disseminations and stockwork quartz veinlets in biotite feldspar porphyry (BFP) and in the surrounding Hazelton volcanic country rock. The host rocks contain biotite and quartz, sericite alteration. Drilling of this deposit by Texas Gulf Sulphur and Canadian Superior Oil in 1968 indicated a geological reserve of 60 million tonnes grading 0.16% copper, 0.1 g/tonne gold, which includes a higher grade core of 16 million tonnes grading 0.32% copper, 0.1 g/tonne gold (at 0.2% copper cutoff).
6. The breccia pipe, situated within the porphyry-copper stockwork, consists of angular clasts up to several tens of centimetres in size of biotite-feldspar-porphyry and Hazelton volcanics. Open space in the breccia prior to mineralization was estimated (Ogryzlo 1991) at 5 to 20% of rock volume.

.../2

SAMPSON ENGINEERING INC.

2696 West 11th Avenue
Vancouver, B.C. V6K 2L6

Chalcopyrite and pyrite and lesser chalcocite had been deposited in the space between the angular clasts. The largest observed cavity filled with chalcopyrite is in the order of 60 centimetres wide and graded 16% copper. Copper grades appear to be highest adjacent to the hanging wall, which may have acted as a trap for the mineralization. Grades drop towards the footwall where the porosity is plugged with dolomite and rock flour.

7. Drilling of the breccia pipe by Noranda (1989, 1990) intersected 22.9 m. assaying 2.75% copper in hole 89-1 but Noranda concluded that the breccia body is cut out at 70 to 80 metres depth by an intrusion of white massive quartz biotite-feldspar-porphyry, and allowed their option to expire.
8. Subsequent drilling of the breccia pipe by David Chapman (1991) indicated that the area of mineralized breccia may extend to greater depth than that indicated by the Noranda drilling. Of the 7 holes drilled by Chapman only one (91-2) has been assayed (by Kennecott Canada 12 Oct. 91 - See Appendix A). This showed good grade copper mineralization to the bottom of the hole (103.32 m., 339 ft.) and included a 50 m. section which assayed 2.30% Cu (Ogryzlo 1993). In addition several 10 ft. sections contained appreciable amounts of gold in the 0.01 to 0.05 oz/ton range, with one section (160-170 ft.) assaying 0.46 oz/ton gold.
9. The writer's February 1993 report concluded that although the Copper Molybdenum stockwork porphyry deposit is too low in copper and gold grades to be mineable economically, the breccia pipe carries economic grades in both metals. It has been well delineated in lateral extent by drilling but may extend to greater depth than indicated by Noranda's drill programmes in 1989 and 1990.
10. In porphyry systems, breccia pipes rarely occur in isolation. Ogryzlo (1993) pointed out similarities between the breccia body and those occurring at the Cananea deposit Mexico, where several breccia bodies occur along an arcuate structure. The potential for occurrence of other

breccia bodies at Hearne hill is thus considered very high. The geophysical and geochemical surveys on the property were at wide spacing (800 ft. line spacing with some infill at 400 ft.) but despite this wide spaced coverage they showed several untested geochemical and IP (Chargeability) targets which could represent breccia bodies.

11. In order to explore for other breccia pipes, in summer/fall 1993 Booker Gold carried out the following exploration programmes:

- a) Trenching

A John Deere 892 backhoe excavated 14 trenches in the vicinity of the mineralized breccia and to the north and east. Mineralization exposed by the trenching programme consists of fracture filling and disseminated copper mineralization in altered Feldspar Porphyry (Babine Igneous Suite) and altered Hazelton andesite volcanic country rocks. Although no mineralized breccia similar to that occurring in the main breccia body was discovered in bedrock, several boulders containing chalcopyrite, pyrite, chalcocite in a breccia strongly resembling that in the main breccia pipe were discovered in overburden consisting of rock slide material in trenches TR93-4 and TR93-5 up slope, i.e. approx. 100 to 200 ft. elevation above the main breccia body.

Samples from the mineralized boulders assayed as high as 20.603% copper, 0.146 oz/ton gold and 1.75 oz/ton silver. Because the boulders are situated above the main breccia zone in rock slide debris which overlies glacial till, they are not considered to be derived from the known breccia body but are probably from an as yet undiscovered mineralized breccia situated to the northeast of the trenched area.

- b) Percussion drilling:

Programmes of percussion drilling were done in May/June, 27 July - 7 August and late October. Twenty-one holes totalling 3010 ft. explored the mineralized breccia and surrounding area. Samples of cuttings were

taken for each 10 ft. run and assayed for copper and gold. Hole PH20 drilled on the main breccia body intersected 230 ft. which assayed 2.118% copper, 0.014 oz/ton gold.

c) Magnetometer survey:

In 27 September - 5 October and 1-3 November a magnetometer survey was run over the main breccia body and the area north and east. The contoured magnetometer map shows a pronounced mag low associated with the breccia pipe. It also indicates a mag low 600-700 ft. east of the breccia pipe of similar dimensions and intensity which may represent another breccia pipe.

12. In the 20 February 1993 report Phase 1 and 2 exploration programmes recommended geological mapping, 2000 ft. percussion drilling and geochemical soil sampling (1000 samples).

Booker Gold did the geological mapping and over 3000 ft. of percussion drilling. Based on field observations and results, it was decided by Booker Gold personnel and the writer that trenching programmes and a magnetometer survey would be more successful than further geochemical soil sampling. The programmes done in 1993 by Booker Gold although somewhat altered from the original proposed Phase 1 and 2 considerably exceed the original expenditures proposed and the writer thus considers that Phases 1 and 2 have been successfully completed.

RECOMMENDATIONS AND COST ESTIMATES

1. Extensions of the magnetometer survey to the north and east is recommended because:
 - a) the mag low located by the 1993 survey needs defining and closing off. Since it is due east of the known breccia, an east-west structure may be present.
 - b) the known breccia body is elongated 010 to 020, i.e. it may be on a fracture zone which strikes in that direction.
 - c) the area northeast of the main breccia is up slope and is covered by rock slide debris.
 - d) the geochemical and geophysical compilation map (Figure 7) shows strong copper values in soils and high chargeability I.P. open to the northeast of the main breccia.

2. Trenching of targets located by the magnetometer survey followed by diamond drilling is recommended. Cost estimates are as follows:

	<u>\$</u>
Magnetometer Survey: Rechain north south lines and cut new lines where required. Flag additional east west lines: 20 days at \$500/day (includes report preparation)	10,000
Interpretation, selection of targets, supervision, etc.	5,000
Trenching: 10 days at \$1000/day backhoe rental	10,000
Mapping, sampling, analyses, travel, etc.	10,000
1000 m. (3000 ft.) NQ diamond drilling at \$20/ft.	60,000
Report preparation, supervision, etc.	<u>5,000</u>
	<u>\$100,000</u>

1. INTRODUCTION

"Report on Geology, Exploration Results and Potential of the Hearne Hill Property" (Sampson 20 Feb. 1993) concluded that previous exploration programmes on Booker Gold's Hearne Hill property had located a porphyry-molybdenum deposit which is of sub-economic grade, but which contains a breccia body carrying economic copper and gold grades. Programmes of exploration were proposed in order to explore the property for other breccia bodies.

During the summer and fall of 1993, Booker Gold personnel carried out programmes of geological mapping, trenching, percussion drilling and magnetometer geophysics in order to explore the known breccia zone and try to locate other mineralized breccias. The writer accompanied Hugh Grenfall, president of Booker Gold, on two visits to the property, and examined the trenching, results of percussion drilling, and mapped the geology of the area surrounding the known breccia zone. This report is thus based on field examinations, supervision of work programmes carried out in 1993, and examination of assay results produced by the trenching, percussion drilling programmes and results of the magnetometer geophysical survey.

2. PROPERTY, LOCATION, ACCESS, CLIMATE

The Hearne Hill Property (also known in old reports as Kofit) is situated as follows:

Latitude	Longitude	Average Elevation	NTS
55°11'N	126°16'W	3600 ft. (1100 m.)	93-M-1W

The property consists of two metric unit claims, and 17 two post claims:

Name of Claim	Units	Record Number	Expiry Date
Hearne 1	15	12662 (242812)	7 Oct. 1999
Hearne 2	15	12663 (242813)	7 Oct. 1999
PB1	1	321701	20 Oct. 1994
PB2	1	321701	20 Oct. 1994
PB3	1	321703	20 Oct. 1994
BG1	1	317528	16 May 1994

6	1	317533	16 May 1994
7	1	317534	16 May 1994
8	1	317535	16 May 1994
HG1	1	319913	11 Aug. 1994
2	1	319914	11 Aug. 1994
3	1	319915	11 Aug. 1994
4	1	319916	11 Aug. 1994
5	1	319917	11 Aug. 1994
6	1	319918	11 Aug. 1994

The property is situated on the western slopes of Hearne Hill, approximately 65 kms. northeast of Smithers in central British Columbia.

It is accessible by road from the former producing Bell Mine site. The Northwood pulp and timber logging road on the eastern side of Babine Lake provides year-round access to within 4 kilometres of the property. A four-wheel drive exploration road intersects the Northwood road at kilometre 40, 21 kilometres north of the Bell Mine site. This intersection is approximately one kilometre east of the Morrison bridge. Access is then gained by 4-wheel drive vehicle for an additional distance of 4 kilometres north to the 3600 ft. elevation on the Hearne Hill property.

 BY: C.J.S. SCALE: 1:50,000 FIGURE: 3

The Bell Mine property is accessible from Smithers, B.C. by 150 kilometres of paved road (via Houston) to the village of Granisle. Access is then a further 14 kilometres by gravel road to the Noranda Minerals ferry slip on the western shore of Babine Lake. Year-round access to the Bell Mine site is by a further 3.5 kilometres ferry crossing of Babine Lake.

An alternate access route is from Smithers to Topley Landing, then by Northwood barge across Babine Lake and via the Nose Bay, Hagan, Jinx and Nak roads to the Hearne Hill road.

The property varies in elevation from a low of 734 m. (2405 ft.) on Morrison Creek on the west side to a high point of 1350 m. (4430 ft.) on Hearne Hill on the east side of the property. Hearne Hill forms part of ridge trending northwest/southeast caused by the block faulting in the area. The western slope of the ridge which forms much of the Hearne Hill property is quite steep and drained by several small creeks which drain westward into Morrison Lake.

3. EXPLORATION HISTORY

The Babine Lake area has been actively explored since the 1920s. In the 1950s and 1960s, British Columbia experienced an exploration boom for porphyry-copper deposits. The Babine Lake area was intensely explored by programmes of prospecting, geophysics and geochemistry, which resulted in the discovery of many porphyry-copper deposits, two of which - Granisle and Bell - were subsequently placed in production. The Granisle Mine, which was discovered by Granby (later Zapata-Granby, and eventually sold to Noranda as part of Bell Copper Division) started production in 1955 at 5000 TPD, subsequently increased to 14,000 TPD. The mine closed in 1982. The Bell Mine of Noranda Minerals was commissioned in 1972 at 10,000 TPD, which was subsequently increased to 17,000 TPD by 1980. It was closed in 1992 and is currently kept on a care and maintenance basis.

Reserves at start up at Granisle were 94 m. tons 0.43% Cu, 0.004 oz/ton Au at Bell 128 m. 0.48% Cu, 0.010 oz/t Au (Sinclair, Carter, Dawson - A preliminary analysis of gold and silver grades of porphyry type deposits in Western Canada. Assoc. of Exploration Geochemists 1982).

The presence of copper mineralization at the Hearne Hill property has been known for many years. In 1967, Trojan Consolidated Mines and Buttle Lake Mining did magnetometer and soil sampling surveys over the property (Dirom 1967). This was followed up by bulldozer trenching which discovered the breccia boulders (identified as "discovery showings" on maps of the property - Trench T93-3).

The property was optioned by Texas Gulf Sulphur Company who did programmes of IP, magnetometer and diamond drilling (12 holes totalling approx. 6,000 ft. (1942 m.) in 1968. The drill programme indicated presence of a Babine style porphyry-copper deposit on the Hearne Hill property, similar to the Bell, Morrison, and Granisle deposits. Texas Gulf calculated the overall grade of the porphyry deposit at 0.2% copper, but drilling apparently failed to intersect the mineralized breccia, although according to Ogryzlo (1990) the lower portion of HH1-1967 apparently intersected the dolomite cemented footwall portion of the breccia pipe. Texas Gulf Sulphur considered that the copper grade was not sufficiently high to support exploitation of the deposit.

In 1968 the property was optioned by Canadian Superior Exploration, who did geological mapping, induced polarization, magnetometer and geochemical sampling surveys, followed by some preliminary diamond drilling (Kahlert and Fawley 1968). Canadian Superior followed this with a programme of percussion drilling in 1969 (Kahlert 1969).

The property then lay dormant for many years until it was acquired by Dave Chapman in 1989. He carried out a limited programme of trenching on the old showings with a skidder mounted backhoe and rekindled interest in the property.

In July 1989 Noranda Minerals and Bell Mine (a Noranda Mines subsidiary) optioned the property. They re-established the original Texas Gulf line grid and carried out a programme of geochemical soil sampling to relocate the original anomaly, which is essentially in place over the mineralization. This was followed by a programme of diamond drilling consisting of 6 holes totalling 1537 ft. (468 m.) fall 1989 in order to establish whether the mineralization in the breccia pipe exposed at surface had any vertical continuity and secondly to establish the attitude of the mineralization.

As reported by Ogryzlo (January 1991) 4 holes intersected the mineralization. Hole H89-1 was lost in mineralization at 270 ft. (82 m.) when the rods stuck in a mud seam. The last core run was recovered including the mud seam which assayed 3.32% copper. Significant intersections from the 1989 drilling programme are summarized as follows:

SUMMARY OF RESULTS - 1989 PROGRAMME

HOLE NUMBER	FROM feet(meters)	TO feet(meters)	WIDTH feet(meters)	% Cu
H89-1	190.0(57.9)	227.5(69.3)	37.5(11.4)	1.34
	227.5(69.3)	270.0(82.3)	42.5(12.9)	3.61
H89-2	45.0(13.7)	65.0(19.8)	20.0(6.1)	1.84
	65.0(19.8)	85.0(25.9)	20.0(6.1)	2.68
	85.0(25.9)	130.0(39.6)	45.0(13.7)	1.10
H89-3	60.0(18.3)	77.5(23.6)	17.5(5.1)	2.11
H89-4	97.5(29.7)	160.0(48.8)	62.5(19.1)	0.78

The drilling established that the overall trend of the breccia deposit is N10E. The hanging wall of the breccia pipe dips approximately 70°E, the footwall dips at approximately 80°E.

In 1990 Noranda drilled a further 5 NQ size holes, totalling 2,807 ft. (856 m.) in order to test the vertical extent of the mineralized breccia.

As reported by Ogryzlo (January 1991) hole H90-3 was the only hole to intersect the full width of the breccia. Mineralization was intersected over a width of 80 ft. (24.4 m.) with an average grade of 0.67% Cu, 0.05% Mo and 0.005 oz/ton Au. Holes H90-1 and H90-5 also intersected sections of the mineralized breccia. Much of the target area, however, was largely occupied by post-mineral intrusions of biotite-feldspar-porphyry including a massive unit of bleached white BFP, similar to the post-mineral QFP body that has replaced approximately 1/3 of the Bell ore body. Holes H90-2 and H90-4 also intersected post-mineral intrusions. Significant intersections from the 1990 drill programme are summarized as follows:

SUMMARY OF RESULTS - 1990 PROGRAM

HOLE NUMBER	FROM feet(meters)	TO feet(meters)	WIDTH feet(meters)	% Cu
H90-1	340.0(103.6)	400.0(121.9)	60.0(18.3)	0.39
(includes)	372.5(113.5)	395.0(120.4)	17.5(5.3)	0.59
H98-2	380.0(115.8)	691.0(210.6)	311.0(94.7)	0.18
H90-3	80.0(24.4)	390.0(118.9)	310.0(94.5)	0.31
(includes)	305.0(93.0)	385.0(117.3)	80.0(24.4)	0.67
H90-4	110.0(33.5)	465.0(141.7)	355.0(108.2)	0.22
H90-5	Weakly mineralized over		557.0(169.8)	0.11
(includes)	minor breccia		5.0(1.5)	0.56

Noranda concluded that the breccia pipe is of limited size, both in a horizontal and vertical direction and the mineralization has been partially replaced by unmineralized BPF intrusives. Their option expired 1 January 1991.

David Chapman in 1991 drilled 7 diamond holes totalling approximately 550 metres in the breccia zone, of which hole 91-2 intersected 50.0 metres assaying 2.3% Cu. This included one 10 foot section which assayed 0.401 oz/ton gold.

4. REGIONAL GEOLOGY

The Hearne Hill area is situated on the northern edge of the Skeena Arch in a region which is underlain by volcanic and epiclastic rocks ranging in age from lower Jurassic (Telkwa) formation to lower Cretaceous (Skeena) group. This sequence of rocks has been cut by a generally northwest trending series of faults that have created a long linear sequence of horsts and grabens, and the rocks have been intruded by a variety of intermediate to felsic stocks, plugs and dikes of Eocene age (Richards 1990). The geological setting has been described by Tipper and Richards (1976).

The Tertiary, Eocene - 50 m.a., Biotite-Feldspar-Porphyry plugs and stocks of the Babine igneous suite were emplaced along major faults in a continental magmatic arc. Two ore bodies (Bell and Granisle) and numerous sub-economic deposits (Morrison and Hearne among others) occur as porphyry-copper deposits which are temporally and spatially associated with the Babine igneous suite intrusions (Carson and Jambour 1973). The Babine igneous suite is a high potassium, calcalkaline suite which show some trace elements normally associated with alkaline porphyry coppers rather than calcalkaline.

5. PROPERTY GEOLOGY, MINERALIZATION AND ALTERATION

The following description of geological setting, mineralization and alteration is based on Ogryzlo 1991 as follows:

5.1 Geological Setting:

Hearne Hill is underlain by volcanic rocks of the lower to middle Jurassic Hazelton Group (Richards, 1973). The volcanic rocks on the property have been tentatively associated with the submarine Kotsine facies of the Sinemurian Telkwa formation (Tipper and Richards, 1976). The volcanic rocks are characterized by waterlain grey lapilli-crystal tuffs and grey andesite. Associated sedimentary rocks are gritty greywackes, green siltstones and buff felsic tuff.

These rocks have been intruded by prophyritic intrusions of the 50 my Eocene Babine igneous suite. Mapping by Booker Gold shows that the Eocene biotite-feldspar prophyry (BFP) intrusives are in the form of a series of northeasterly trending dykes. The intrusives are compositionally equivalent to a diorite or a quartz diorite. The BFP that is exposed on the 300N baseline near 300E is a dark, hard, biotitized BFP similar to rocks observed in the Morrison Lake deposit. There is no well defined intrusive center of the BFP similar to the centers noted at the Bell Mine (Carson et al 1976) and at the Morrison deposit (Carson and Jambour, 1976). Porphyry copper related mineralization consists of chalcocite, and minor bornite filling fractures, minor disseminations of chalcopyrite, and traces of molybdenite. The style of mineralization suggests a relatively deep setting for the environment of emplacement.

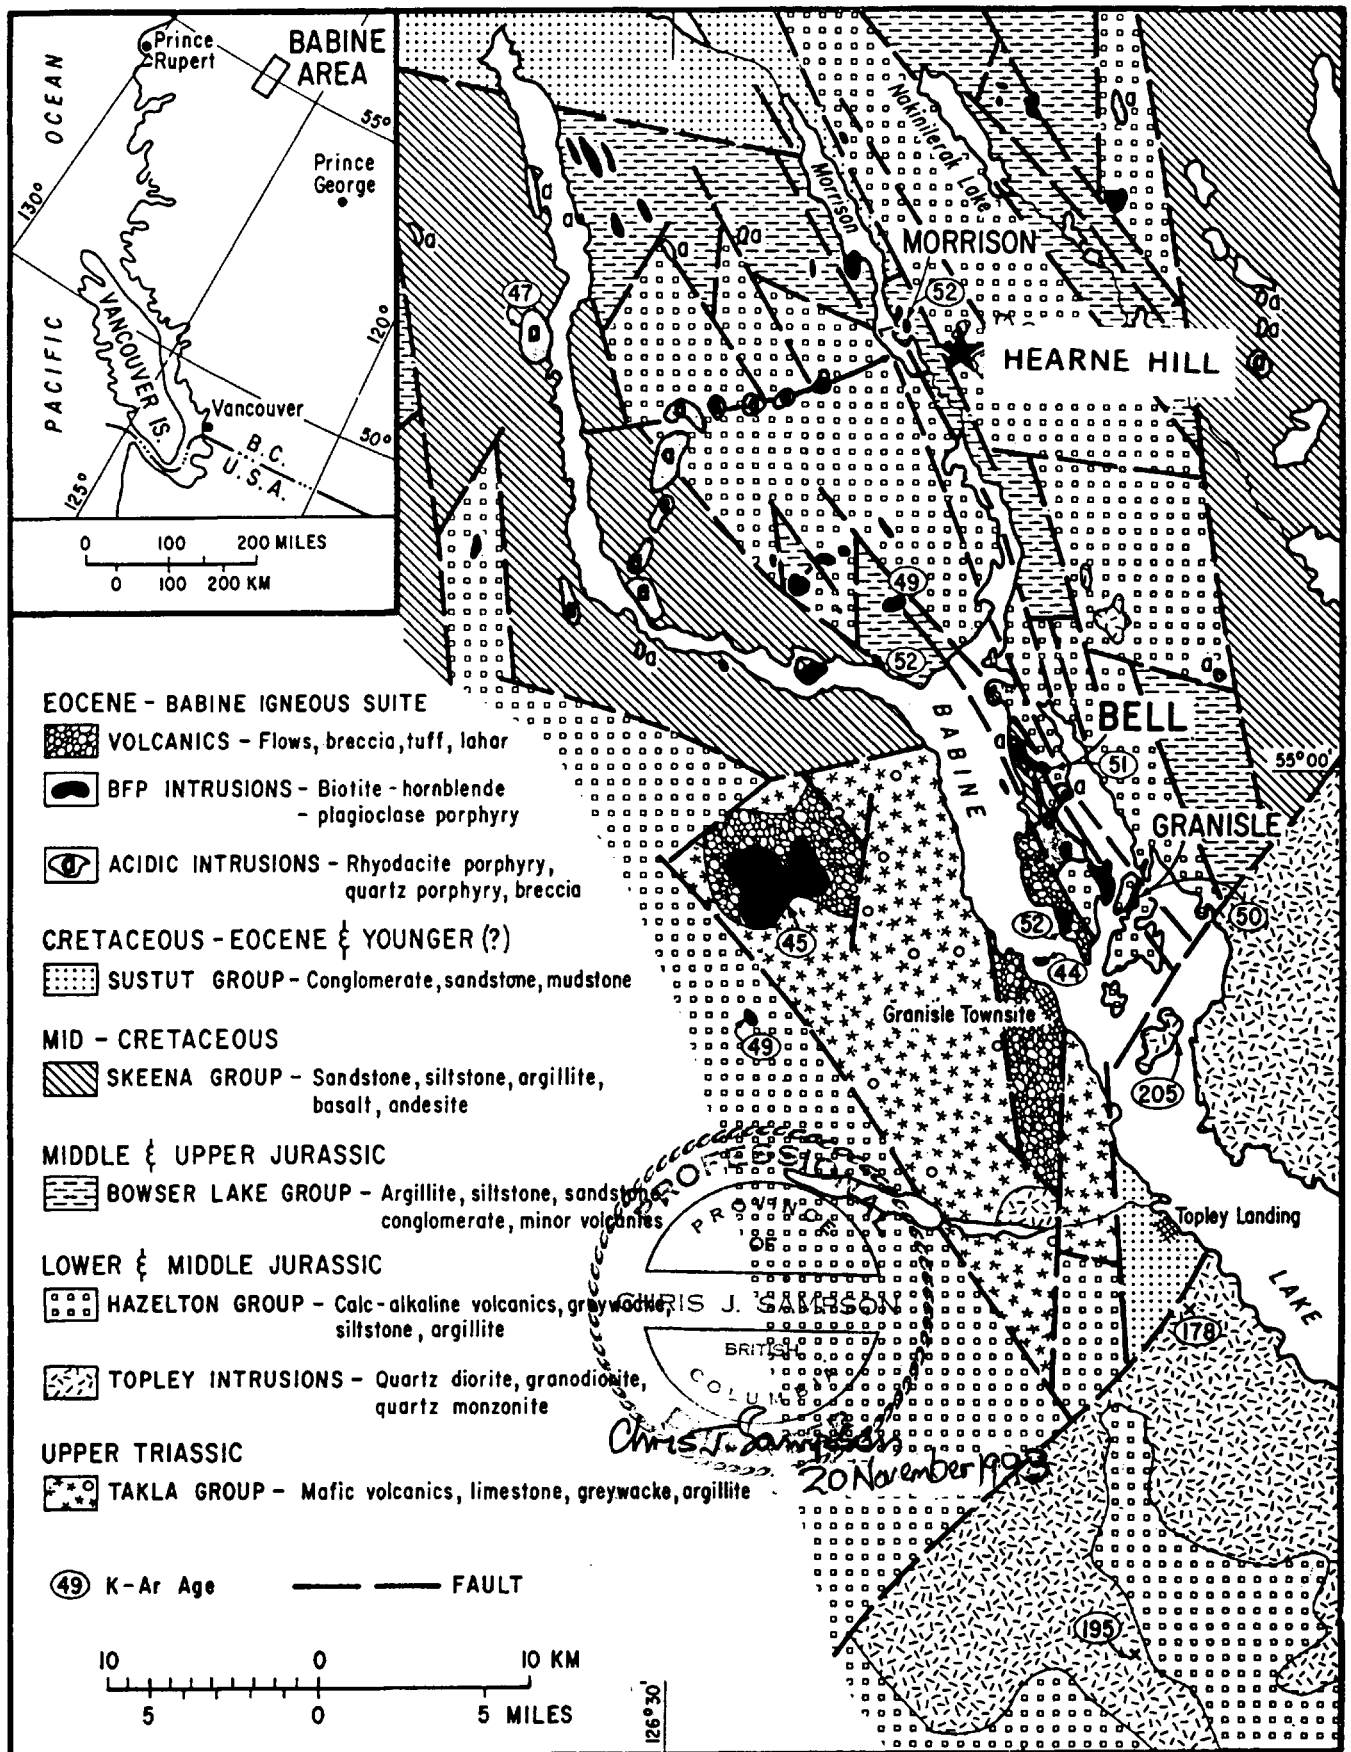

FIGURE 4 - Geology of the Northern Babine Lake Area and Location of the Hearne Hill, Morrison, Granisle and Bell Copper Porphyry Deposits, K-Ar age determinations are after Carter (1974) and the Geological Survey of Canada. (From: CIM Special Volume No.15)

FIGURE: 5

A distinctive phase of the BFP intrusions appears to be either very late or post mineral in age. The rock is a massive white BFP with intense sericite-pyrite alteration. Plagioclase is soft, white, and completely altered to sericite. Biotite is bleached pale brown to white and is sericitized as well. The massive unbroken structures suggest that the rock was emplaced after the structural events that are evident in most of the other units observed. The rock is similar in appearance to the QBFP (QFP) post mineral phase that occupies the southeastern portion of the Bell orebody, but lacks the quartz phenocrysts.

Ogryzlo concluded that the intrusions on Hearne Hill are multiphase, with more than one intermineral or post mineral intrusion of BFP.

5.2 Mineralization

Two styles of mineralization are present: These are:

1. Porphyry Copper Mineralization

Chalcopyrite, bornite and molybdenite occur as fracture fillings and disseminations in the biotite feldspar porphyry and the adjacent volcanics. This mineralization is due to a large but weakly developed porphyry copper system of the Cu-Mo type.

During the 1990 program, it became evident that many of the biotite feldspar porphyry units observed in the drill core were intermineral or post mineral in age. The erratic nature of the copper distribution is caused by these late stage intrusions. The volcanic rocks in contact with late stage BFP are invariably higher in grade. The volcanics (Hazelton, i.e. Jurassic) were deposited long before any mineralizing event, and have been subjected to all stages of mineralization. When the distribution of copper in the volcanics alone is examined, it appears that grades are increasing to the south and west of the breccia pipe.

Ogryzlo concluded that mineralization trends in the volcanics deserve far more study. Grades are within the range of grades occurring in volcanics adjacent to the Bell and Granisle deposits, namely from 0.15% to 0.40% Cu. Although the

distribution of mineralization is greatly complicated by the post-mineral intrusions, there is still potential for the development of a porphyry copper deposit. Pursuit of grade trends in the volcanics could indicate a center of mineralization.

2. Breccia Mineralization

Chalcopyrite occurs filling open spaces between rock fragments in a clast supported breccia. Open space in the breccia prior to mineralization comprised 5% to 20% of the volume of the rock. Interclast porosity remains at 2% to 8% of the volume of the rock. Pyrite also occurs as breccia cement, but is subordinate to chalcopyrite. Pyrite disappears as breccia cement at depth, with chalcopyrite along with lesser chalcocite being the only sulphide species present.

The largest observed cavity filled with chalcopyrite is in the order of two feet (50 centimeters) and grades 16% Cu. Copper grades are highest adjacent to the hangingwall, which may have acted as a trap for the mineralization. Grades drop dramatically towards the footwall, where the porosity is plugged with dolomite and rock flour.

There appears to have been little movement or milling of the clasts. The breccia fragments appear to have simply accumulated as a subterranean talus that caved from the roof in a large cavern or steeply dipping pipe. The mode of formation of the pipe is uncertain. It is possible that the void resulted from solution of the rock by circulating corrosive fluids related to the porphyry copper mineralization seen elsewhere on Hearne Hill.

Supergene processes have redistributed the copper grades. The oxidized breccias in the surface trenches reveal limonite cement replacing sulphide open space filling. Malachite and azurite may also be seen as breccia cement. Chalcocite may be seen as rims of chalcopyrite in most breccia cavities, and rarely may be seen almost completely replacing masses of pyrite. Total sulphide content in the breccia is 10% to 15%, of which up to 1% may be comprised of chalcocite.

Ogryzlo concluded that "the mineralization has been derived by solution and redistribution of the porphyry copper mineralization found in the carbonate cemented clasts that collected against the footwall. Although these clasts are lithologically identical to the wallrocks, copper grades in the footwall breccia are in the order of 0.01% Cu to 0.3% Cu as compared to 0.10% Cu to 0.20% in the adjacent rocks from which they were apparently derived. The carbonate open space filling appears to post date the sulphide open space filling.

The breccia clasts may be lithologically identical to the enclosing wallrocks, making the breccia virtually monolithologic. Heterolithic breccia were observed in holes H90-3 and H90-1. Sericitized and bleached biotite feldspar porphyry clasts with grey andesite and tuffaceous felsic clasts form the bulk of the pipe. The only control on the location of the pipe appears to be the contact between the biotite feldspar porphyry and the volcanics. The greater proportions of volcanic clasts occur closer to the contact. Many clasts reveal pre-breccia mineralization consisting of sulphide and quartz sulphide veinlets. (It should be noted that the volcanics have been mapped as "hybrid diorite" in earlier assessment reports.)

Ogryzlo (1993) subsequently estimated the breccia body to contain a drill indicated resource (i.e. geologic reserve) of 143,000 tonnes grading 0.74% copper and 0.9 g/tonne gold.

6. 1993 EXPLORATION PROGRAMMES

During summer and fall 1993, Booker Gold carried out programmes of percussion drilling, trenching, magnetometer geophysics and geological mapping. These programmes are described as follows:

6.1 Trenching

From 14-22 July and 20-24 September 1993, Booker Gold used a John Deere 892 backhoe operated by Ira Bowd and owned by Ernie and Kevin Dubrak to excavate 14 trenches in the vicinity of the mineralized breccia body. The trenches were mapped and sampled in detail by Mr. J. Cam Steven and the writer. Location, geology and sampling results of the trenching programmes are shown in Figure 9.

The trenching programme extended the area of the known breccia pipe to NE and SW and confirmed the geology of the area to the east and north of the originally located area of showings.

The programme located a shear/breccia zone in trenches 93-4, 93-5, 93-9, 93-6, and 93-8. This strong shear/breccia zone, 30-50 feet wide which strikes approximately N30E, contains only low copper and gold values. Breccia fragments consist principally of altered andesite derived from the country rock. It is a different type of breccia from that seen in the main zone, and is probably of tectonic origin.

All mineralization exposed by the trenching programme in bedrock consists of fracture filling and disseminated copper mineralization in altered Biotite Feldspar Porphyry and andesite country rock. Apart from the breccia body described in the previous paragraph, no breccias resembling the main mineralized breccia were discovered in bedrock.

In trenches 4 and 5, however, boulders of mineralized breccia up to 1.5 m. size were encountered in overburden. This breccia very strongly resembles that occurring in the main breccia zone, namely it consists of fragments of altered biotite feldspar porphyry or andesitic material in a fine grained silicified and

altered matrix which contains chalcopyrite, chalcocite and pyrite. Samples from this breccia float assayed as high as 20.603% copper, 0.146 oz/ton gold and 1.75 oz/ton silver. The trenches are situated up slope from the main breccia body, i.e. the breccia boulders are some 100-200 feet higher in elevation than the top of the main breccia zone. The entire area explored by trenches 93-14, 4, 13, 5, 5A, 6, 9 and 10 plus the areas to the north and east are covered by extensive rock slides which apparently have travelled down the mountain side from the east and northeast. It was concluded from the field evidence that the mineralized breccia boulders seen in overburden at TR93-4 & TR93-5 are not derived from the main breccia zone because they are situated well above it. They probably originated from another mineralized breccia body which lies to the north-northeast or east of the known breccia zone.

Trench No.	Length Sampled(ft)	Distance(ft)	ASSAY		
			Copper%	Gold oz/t	Silver oz/t

6.2 Percussion Drilling

Percussion drilling was done on the property in late May - early June, 27 July - 7 August and in late October. 21 holes, totalling 3010 feet, were drilled. Locations are shown on Figure 8. Cuttings were sampled from each 10 foot run and assayed for copper and in some cases for gold. The following table shows assay results averaged over the length of each hole.

DRILL HOLE	INTERVAL (ft)	LENGTH (ft)	ASSAY	
			COPPER ppm(%)	Gold ppb (oz/t)
PH1	40-100	60	89	11
PH2	30- 90	60	92	8
PH3	10-100	90	134	19
PH4	10-160	150	186	37
PH5	30-110	80	1642	91
PH6	20-150	130	337	8
PH7	20-110	90	554	17
PH8	20-150	130	243	7
PH9	20- 50	30	130	7
PH10	20-160	140	404	11
PH11	20-100	80	1195	36
PH12	10- 40	30	977	20
PH13	30-200	170	(0.214)	
PH14	20-200	180	(0.164)	
PH15	20-120	100	(0.083)	
PH16	20-150	130	(0.074)	
PH17	20-210	190	(0.154)	54
PH18	20-200	180	(0.115)	34
PH19	20-210	190	(0.028)	
PH20	20-250	230	2.118	(0.014)
PH21	<u>10-150</u>	140	0.546	(0.008)

3010 ft.

The percussion drilling programme generally confirmed the known distribution of copper mineralization with the exception of PH5 which intersected 80 feet of mineralized altered volcanic assaying 1642 ppm copper and 91 ppb gold in an area well to the south of the previously assumed limit of porphyry-copper mineralization. In addition, hole PH20 drilled on the downdip extension of the main breccia zone intersected significant copper and gold mineralization, as follows:

FOOTAGE	% COPPER	FIRE GOLD oz/ton	METALLIC AVG. GOLD oz/ton
20- 30	2.058	.026	.050
30- 40	4.535	.029	.043

240-250	2.503	.011	.012
	END OF HOLE		

6.3 Magnetometer Survey

During 27 September - 5 October and 1-3 November, a magnetometer survey using a Scintrex MP2 proton procession magnetometer was run between 289N to 297N across the main breccia body and in the area to the north and east (Figure 10). Readings were taken at 10 foot intervals along the 50 foot spaced east-west lines, i.e. a total coverage of 13,200 lineal feet. The contoured magnetometer map (Figure 10) shows a well defined magnetometer low, associated with the main breccia body. It also indicates presence of another similar magnetic low feature situated on the extreme eastern side of the magnetometer grid, 600-700 feet east of the main breccia body. This magnetometer feature will be investigated by the exploration programme, proposed in this report.

7. CERTIFICATE

I, Christopher J. Sampson, of 2696 West 11th Avenue, Vancouver, B.C., V6K 2L6, hereby certify that:

1. I am a graduate (1966) of the Royal School of Mines, London University, England with a Bachelor of Science degree (Honours) in Economic Geology.
2. I have practised my profession of mining exploration for the past 27 years in Canada, Europe, United States and Central America. For the past 17 years I have been based in British Columbia.
3. I am a consulting geologist. I am a registered member in good standing of the Association of Professional Engineers of British Columbia.
4. I have not written other reports on the Hearne Hill Property nor on other properties within 10 kms. of the claims.
5. The present report is based on study of published, unpublished reports, visits to the property, and supervision of work programmes in 1993.
6. I have not received, nor do I expect to receive any interest, direct or indirect, in the properties or securities of Booker Gold Exploration Ltd. or in those of its associated companies.
7. Booker Gold Explorations Ltd. and its affiliates are hereby authorized to use this report in, or in conjunction with, any prospectus or statement of material facts.
8. I have no interest in any other property or company holding property within 10 kilometres of the Hearne Hill property.

Vancouver, B.C.
20 November 1993

Christopher J. Sampson, P.Eng.
Consulting Geologist

APPENDIX B

1993 ASSAYS AND ANALYSES:

File Number	Date	Description
93-0965	1 June 1993	Percussion Holes PH1 to PH2
93-1712	3 August 1993	Chip Samples Trenches T93-2 to T93-5
93-1900	16 August 1993	Percussion holes PH13 to PH19
93-1907	17 August 1993	Trench T93-4 Float Samples
93-2646	1 October 1993	Chip Samples Trenches T93-7 and T93-14
93-2937	25 October 1993	Percussion holes PH20 and PH21

ICP - .500 GRAM SAMPLE IS DIGESTED WITH 3ML 3-1-2 HCL-HNO₃-H₂O AT 95 DEG. C FOR ONE HOUR AND IS DILUTED TO 10 ML WITH WATER.

THIS LEACH IS PARTIAL FOR MN FE SR CA P LA CR MG BA TI B W AND LIMITED FOR NA K AND AL.

- SAMPLE TYPE: CUTTING AU* ANALYSIS BY ACID LEACH/AA FROM 10 GM SAMPLE. Samples beginning 'RE' are duplicate samples.
