

AGASSIZ SAMPLES

Project M454

S. Yungul

The heavily mineralized specimens are somewhat more Cu rich than average, but pyrite is more common elsewhere in the mineralized zone. Thus we can presume a reasonably typical conductivity for these pieces. The lightly mineralized andesitic breccia would be fairly typical of immediate hanging wall, and this would grade upwards into a true andesite. The argillaceous chunk could be anywhere within, immediately above, or immediately below, the mineralized zone. The piece of drill core is very representative of the footwall

I hope these samples will be adequate.
