Dawe —

I've doctored up the geology map and provided a section and plot of recent work to give you some of our ideas. The strongest geochem on our old data seems to occur at the base of the strongly silicified zone within conglomerate. If you are detail mapping, sample # C654 went 40 ppb Au and may represent (if real) a lead into something under the hill (to the west). You may want to map this area in detail.

I've spotted 3 more drill holes tentatively - but final position should rely on geochem results. ~~The other~~ feature that has not been mapped is shear zones. A few have been seen but their importance unknown. To the north of DDH #1.

My results are on the Xerox copy of the topo map. Bill's are on the mylar overlay.

Good luck.

Gord.
