

WINDY CLAIMS - 93J/13W

Brinco Report by R. Hewton

General area is underlain by Takla Group andesite and basalt flows and tuffs of Triassic age. Granitoid gneiss, pegmatite and garnetiferous chloritic schist occur 6 km east.

From samples collected rock is diorite with greenschist facies alteration. Shears are sericitic. Veinlets and patchy networks of epidote are common. Chalcopyrite associated with epidote.

High gold apparently positively correlated with alteration. Samples in river low gold, low alteration; those from higher up w/ more alteration have higher gold values.
