Dear Kim:

Enclosed with this letter you will find two specimens of high-grade ore from Blackdome. Both will have visible gold in them, although the grains are easily dislodged and could be lost during cutting. Careful cutting should yield pleasing results, however. You will also note that one of the specimens has a significant sulphide content. This is something that was not seen prior to this winter when we broke into a zone that is deeper than the previously known ore. Pyrite and chalcopyrite are the most common sulphide minerals along with lesser amounts of silver sulphides, galena, specular hematite and electrum. The dark grey fine-grained material is comprised of silver-bearing minerals. They are probably argentite, tetrahedrite and, possibly, aguilarite and/or naumannite. You may also see some chalcocite coating some of the sulphide grains.

When you are finished with these rocks, please forward what is left of them to Tom Schroeter. He has a good collection of Blackdome specimens and I have been promising him a piece of the "sulphide" ore.

Good luck with your presentation!

Sincere regards,

BLACKDOME MINING CORPORATION

  
D. W. RENNIE
