RESUME OF WORK DONE ON TWIN GROUP TO 14/7/70

GENERAL OPENING BLURB

J.C. DOUGLAS ARRIVED AT THE TWIN GROUP CAMPSITE ABOUT 5 P.M. ON JUNE 27 AND SETUP CAMP ~~THAT DAY~~ THAT EVENING AND the next day.

Since then, as per instructions, we have concentrated on sampling the geochemical grid, ~~finding~~ locating claim lines & posts, & geological mapping, in that order of priority.

GEOCHEMICAL WORK TO 14/7/70 BLURB

The grid sampled last year was located. Its baseline (100N) was run along a bearing of 110° (APPROX), with X-lines ~~per~~ per hundred feet apart. The grid ran from coordinates 100E to 124 E. ~~This grid has to~~ J.C. DOUGLAS EXTENDED THIS grid 1200' to the East, {to L136E}, and 4000' to the West, to line 60 E. ~~Lines~~ Lines were run up the slope of mount North for 800' in general. This is in line with the width of last yrs grid. In addition the three lines to the east were sampled south ~~towards~~ until approaching Twin Creek. ~~Sample~~ Lines were run 400' apart as in the old grid. Sample interval was 200'. The lines were chained & compased, with stations being flagged every 100' along both baseline and crosslines. Line 60E runs into the showings discovered last year.

Property location Blurb

A Considerable amount of time was spent locating claim lines and posts. To date 44 of the 54 claims have been located (the

Geology - Resumé from June 27 to July 15

Geological mapping of the Twin Group between June 27 to July 15 consisted of locating outcrops on the geology geochemical sampling grid, relating these to the geological map prepared last year of the Twin Group and becoming familiar with the rock types established last year. ~~Several~~ Outcrops which were not on last years map have been plotted. The majority of these are in the NE corner where the rocks correspond to the #2 fine to med. grain border phase. In one place on the NE part a continuation of the #4 qtz. feldspar porphyry outcrops (between line 120+124E at 116N). Twenty feet from the baseline on line 74E there is a small outcrop of #1 volcanic. This is the most northern outcrop of this #1 type + although no contact between #1 & #2 is observed, it seems that the contact may be in the valley. Further geological mapping was done in unmapped areas as when the claim lines were being followed to locate their positions. In claim 34, 100' above the beaver pond there is outcrop, the northern part of which is feldspar porphyry, the southern part, the #2 border phase. In claim 36, 100' south of the main stream there is a 400' ridge like outcrop area of #2 border phase type. These outcrop locations show that the #1 - #2 contact either dies out along the "camp" valley or is directed S where the two streams meet. Following the southernmost claim line into the N-S valley to the W., the steep slope is covered by numerous boulders for several hundred feet to the claim boundary. These boulders are granitic. On the northernmost claim line a similar boulder slope was encountered for 1500' from the W boundary East. 1900' E of the boundary there is a small ote of #2 border phase. ~~was encountered~~
