ECSTALL PROPERTY, B.C. - Exploration on the 100%-owned Ecstall property, located 72 km southeast of Prince Rupert is continuing. Work has focused on two areas - Thirteen Creek and Red Gulch. Disseminated and vein-type copper mineralization has been discovered in the Thirteen Creek area. A program of detailed mapping and rock-chip sampling across the zone has indicated copper values in the order of 0.1% to 0.7% across widths from 30 to 100 metres. The host rocks are believed to be sheared intrusives (diorite) and volcanic rocks. The target is believed to be similar to the Gibraltar "porphyry" deposits. Drill sites have been constructed along the two-km long zone and drilling will start when surface surveys have been completed.

Preliminary detailed mapping and sampling in the Red Gulch area has indicated the Ecstall deposit (7,000,000 tons of 0.6% copper, 2.5% zinc, 0.5 grams gold/tonne and 20 grams silver/tonne) is a volcanogenic massive sulphide deposit hosted in metamorphosed volcanic and sedimentary rocks. Large high grade boulders (values up to 23% copper and 0.2 oz. gold/ton) discovered in the Red Gulch indicate significant areas of ore-grade mineralization may exist adjacent to or along strike from the Ecstall Deposit. Further mapping, sampling and prospecting is ongoing. Atna staked 172 additional claim units in the Ecstall area this summer. With a warm coastal climate and low elevation, exploration

of the Ecstall property will continue until late in the year.

Atna has completed a private placement of 487,500 units at \$0.40 per unit. The \$195,000 raised will be used to explore Atna's Ecstall and Yukon properties. (SEE GCNL NO.174, 12Sept94, P.2 FOR PREVIOUS PROJECT INFORMATION)
